Effect of extracts from araticum (Annona crassiflora) on CCl₄-induced liver damage in rats

Influência dos extratos etanólicos de araticum (Annona crassiflora) na atividade das enzimas hepáticas de ratos intoxicados por CCl₄

Roberta ROESLER¹*

Abstract
The influence of ethanolic extracts of Annona crassiflora on the activities of hepatic antioxidant enzymes was examined. Extracts of A. crassiflora seeds and peel were administered orally (50 mg of gallic acid equivalents.kg⁻¹) to Wistar rats for 14 consecutive days followed by a single oral dose of carbon tetrachloride (CCl₄, 2 g.kg⁻¹). Lipid peroxidation and the activities of hepatic catalase (CAT), cytochromes P450 (CP450) and b5, glutathione peroxidase (GPx), glutathione reductase (GRed), superoxide dismutase (SOD), and the content of glutathione equivalents (GSH) were evaluated. The treatment with CCl₄ increased lipid peroxidation, the level of GSH equivalents and the content of cytochrome b5 by 44, 140 and 32%, respectively, with concomitant reductions of 23, 34 and 39% in the activities of CAT, SOD, and CP450, respectively. The treatment with A. crassiflora seeds and peel extracts alone inhibited lipid peroxidation by 27 and 22%, respectively without affecting the CP450 content. The pretreatment with the A. crassiflora extracts prevented the lipid peroxidation, the increase in GSH equivalents and the decrease in CAT activity caused by CCl₄, but it had no effect on the CCl₄-mediated changes in CP450 and b5 and SOD. These results show that A. crassiflora seeds and peel contain antioxidant activity in vivo that could be of potential therapeutic use.

Keywords: Annona crassiflora; antioxidant activity; lipid peroxidation; CCl₄; liver enzymes.

Resumo
Neste estudo, a influência dos extratos etanólicos de Annona crassiflora na atividade das enzimas hepáticas de ratos foi avaliada. Extratos de casca e sementes de A. crassiflora (50 mg de equivalentes de ácido gálico.kg⁻¹) foram administrados por gavagem a ratos Wistar por 14 dias consecutivos seguidos por uma dose oral única de tetracloreto de carbono (CCl₄, 2 g.kg⁻¹). A peroxidação lipídica, conteúdo de citocromo P450 (CP450) e b5 e a atividade das enzimas hepáticas catalase (CAT), superóxido dismutase (SOD), glutatonia peroxidase (GPx), glutatonia reductase (GRed) e equivalentes de glutatonia (GSH) foram avaliados. O tratamento com CCl₄ aumentou a peroxidação lipídica, o nível de equivalentes de glutatonia e o conteúdo de citocromo b5 em 44, 140 e 32%, respectivamente, bem como reduziu em 23, 34 e 39% a atividade das enzimas CAT, SOD e conteúdo de CP450, respectivamente. O tratamento com extratos de sementes e casca de A. crassiflora em ratos não intoxicados por CCl₄, inibiu a peroxidação lipídica em 27 e 22%, respectivamente, sem alterar o conteúdo de CP450. Em ratos intoxicados por CCl₄, os extratos de A. crassiflora preveniram a peroxidação lipídica, o aumento de equivalente de GSH e o decréscimo na atividade de CAT, mas não tiveram efeito significativo sobre as mudanças induzidas pelo CCl₄ no CP450, b5 e SOD. Os resultados demonstram que extratos de sementes e casca de araticum possuem atividade antioxidante in vivo que pode ser de uso potencial para fins terapêuticos.

Palavras-chave: Annona crassiflora; atividade antioxidante; peroxidação lipídica; CCl₄, enzimas hepáticas.

1 Introduction

Reactive oxygen species (ROS) are products of oxidative metabolism, and their production can be stimulated by radiation and xenobiotic agents derived from air pollution or chemicals such as carbon tetrachloride, paraquat, and cigarette smoke. In the absence of adequate endogenous antioxidant defenses, the propagation of free radical-producing events can lead to the co-oxidation of nucleophilic cellular constituents, and the reaction of secondary lipid autoxidation products with nucleophilic macromolecules such as membrane constituents, enzymes, and DNA (YUAN; KITTS, 1996).

Oxidative stress has been associated with the development of chronic and degenerative diseases including cancer, heart disease, and neuronal degeneration such as in Alzheimer’s disease, as well as being involved in aging (AMES; SHIGENAGA; HAGEN, 1993; 1995; DIAZ; FREI; KEANEY, 1997; LANG; LOZANO, 1998; CHRISTEN, 2000). The potential of antioxidant plants to contribute to human health and to protect against heart diseases and cancer has attracted considerable interest among scientists, food manufacturers, and consumers, and it has led to the development of functional foods with specific health effects (LOLINGER, 1991). Typical compounds with antioxidant activity include phenols, phenolic acids, and their derivatives, flavonoids, tocols, phospholipids, amino acids and peptides, phytic acid, ascorbic acid, pigments, and sterols. Phenolic compounds are primary antioxidants that act as free-radical scavengers (XING; WHITE, 1996).
Annona crassiflora, commonly known as araticum, is a tropical fruit consumed mainly by native people of the Brazilian cerrado (the second biggest biome of Brazil). In previous studies, the seeds and peel of slightly ripe fruit were found to have significant antioxidant activity in various models in vitro (ROESLER et al., 2006). Electrospray ionization mass spectrometry (ESI-MS) also revealed the presence of important bioactive components widely recognized as antioxidants including malic acid, ascorbic acid, caffeic acid, quinic acid, ferulic acid, xanthoxylum, rutin, caffeoyltartaric acid, caffeoyl glucose, and [quercetin + hexose + pentose - H]-1 (ROESLER et al., 2007). The aim of the present study was to assess the protective effect of an ethanolic extract of A. crassiflora seeds and peel in Wistar rats treated with carbon tetrachloride (CCl₄). The protective effect of the extract was assessed by quantifying the level of lipid peroxidation and the activities of antioxidant enzymes such as catalase (CAT), superoxide dismutase (SOD), cytochromes P450 and 5b, glutathione peroxidase (GPx), glutathione reductase (GRed), and glutathione (GSH) equivalents in liver homogenates.

2 Material and methods

2.1 Reagents and standards

All solvents and reagents were purchased from Sigma Aldrich Chemical Co. (St. Louis, MO, USA).

2.2 Plant material

Araticum fruits (A. crassiflora) were obtained from Fazenda Erlow, Km 7, Br 070 in the State of Goiânia, Central-West Region of Brazil. The fruits were harvested on two occasions, with special care to avoid damaging the flesh and were transported to UNICAMP (State University of Campinas) where they were stored at 5 °C until use (usually no longer than two months).

2.3 Preparations of the ethanolic extraction

Undamaged fruits were selected and the peel, pulp, and seeds were manually separated. An amount around 100 g of each part of the fruit (peel and seeds) was cut into small parts, mixed, and extracted twice (for 20 minutes each) with 300 mL of aqueous ethanol (5:95, v/v, water:ethanol) using a household mixer. The extracts were filtered through cotton membranes, and the residue was re-extracted under the same conditions. The residues were kept for additional evaluations. The ethanol was removed from the resulting material by vacuum rotary evaporation at 40 °C. The concentrated ethanolic extracts were lyophilized and stored at −18 °C in amber glass bottles until used.

2.4 Determination of the total phenol content

The total polyphenol content of the extracts was determined by the Folin-Ciocalteu method, which involves the reduction of the reagent by phenolic compounds and the concomitant formation for a blue complex; the resulting absorbance at 760 nm increases linearly with the concentration of phenols in the reaction medium (SWAIN; HILLIS, 1959). Briefly, ethanolic extracts were dissolved in methanol to a concentration of 0.5 mg.mL⁻¹. The samples (0.5 mL) were passed through a 0.45 µm membrane filter and mixed with 2.5 mL of 10 fold diluted Folin-Ciocalteu reagent and 2.0 mL of 7.5% sodium carbonate solution. After incubation for 5 min at 50 °C, the resulting absorbance was measured at 760 nm. Gallic acid was used as the spectrophotometric standard and the total phenolic content of the fruit extracts was expressed as gallic acid equivalents (GAE.100 g⁻¹). The content of phenolic compounds was assayed in triplicate.

2.5 Experimental procedure

Male Wistar rats (230–265 g) were obtained from the Multidisciplinary Center for Biological Investigation (CEMIB) at UNICAMP and were housed under a 12 hours light/dark cycle at 23 °C with free access to food and water. The rats were allocated to one of six groups containing seven rats each. The first group (G1) served as the control, the second group (G2) received CCl₄ alone, the third (G3) and fifth group (G5) received an aqueous solution of A. crassiflora peel extract (50 mg of gallic acid equivalents.kg⁻¹), and the fourth (G4) and sixth group (G6) received an aqueous solution of A. crassiflora seed extract (50 mg of gallic acid equivalents.kg⁻¹) for 14 consecutive days. The dosage of the extract administered was based on the LD₅₀ of polyphenols (BOMBARDELLI; MORAZZONI, 1995). The groups G1 and G2 were given saline solution (0.9%) until the 14th day, whereas the groups G2, G5, and G6 received a single oral dose of CCl₄ (2 g.kg⁻¹) in olive oil (1:1, v/v) 6 hours after the last administration of extract or saline solution (0.9%) on the 14th day. All of the rats were killed with an overdose of anesthetic halotano 24 hours later. The liver was excised and microsomal and cytosolic fractions were prepared by differential centrifugation (OMURA; SATO, 1964) and stored in aliquots at −80 °C until analysis. The protein concentrations of the microsomal and cytosolic fractions were measured by the Lowry method (LOWRY et al., 1951) with bovine serum albumin as the protein standard.

2.6 Lipid peroxidation

Thiobarbituric acid reacts with malondialdehyde (MDA) to form a diadduct (pink chromogen) that can be detected spectrophotometrically at 532 nm (VAN DER SLUIS et al., 2000). The assay used was modified for ELISA microtiter plates, which allowed the analysis of a large number of samples per run. Microsomes were thawed on ice, diluted to a concentration of 1 mg of protein.mL⁻¹ with 50 mM Tris-HCl (pH 7.4) containing 150 mM KCl, and then centrifuged (100,000 g, 60 minutes, 4 °C). The pellet was resuspended in 1 mL of Tris buffer and diluted to a final concentration of 0.5 mg.mL⁻¹, unless stated otherwise (OMURA; SATO, 1964; VAN DER SLUIS et al., 2000; SINGH et al., 2002).

Microsomes (aliquots of 240 µL) were preincubated in a 48-well plate for 5 minutes at 37 °C, after which the lipid peroxidation (LPO) was induced by adding 15 µL of 4 mM ascorbic acid and 15 µL of 0.2 mM FeCl₃. After incubation for 60 minutes at 37 °C, the reaction was stopped by adding 0.5 mL of 0.83% thiobarbituric acid dissolved in...
a solution of trichloroacetic acid (TCA)-HCl (16.8%, w/v, TCA in 0.125 N HCl). LPO was quantified by measuring the thiobarbituric acid reactive species (TBARS) after heating the plates for 15 minutes at 80 °C followed by centrifugation (2,500 rpm, 15 minutes). A 250 µL sample of each incubation was transferred to 96-well plates and the absorption was read at 540 nm (color) versus 620 nm (turbidity correction) using a SpectroMax 340 ELISA reader (VAN DER SLUIS et al., 2000; SINGH; CHIDAMBAR MURTHY; JAYAPRAKASHA, 2002). The results were calculated using an extinction coefficient of 1.56 × 10^5 M⁻¹.cm⁻¹ and were expressed as MDA equivalents. One unit of lipid peroxidation activity was defined as the amount of TBA that was converted to TBARS, and the specific activity was expressed as units.mg⁻¹ of protein.

2.7 Enzyme assays

The total microsomal cytochrome P450 and b5 content was quantified as described by Omura and Sato (1964). Catalase was assayed as described by Aebi (1984); glutathione peroxidase (GPx) and glutathione reductase (GRed) were estimated by the method of Albrecht Wendel (1981). The content of glutathione equivalents was determined by the method of Albrecht Wendel (1981). The superoxide dismutase (SOD) was assayed as described by Misra and Fridovich (1972).

2.8 Statistical analysis

The results were expressed as the mean ± S.E.M., and the statistical comparisons were done using Student’s t-test. A value of p ≤ 0.05 indicated significance.

3 Results

3.1 Body and organ weight and general observations

The oral administration of the extracts did not produce any clinical signs or gross alterations attributable to hepatic toxicity or other organ damage. However, rats that received the seed extract showed some anxiety and were restless, perhaps because of the phenolic acids and their derivatives (caffeic acid, caffeoyl glucose, and caffeoyl tartaric) present in this extract (ROESLER et al., 2007). There were significant differences among the body weight gain of the groups that received seed extract (G4 and G6) compared with the control group (G1). Groups 4 and 6 showed reduction in body weight of approximately 28 and 23% compared with the control. Table 1 shows the body weight, hepatic index, and microsomal and cytosolic protein concentrations of the different groups.

3.2 Influence of A. crassiflora seed and peel extracts on hepatic lipid peroxidation

Enhanced lipid peroxidation associated with a depletion of tissue antioxidants is characteristic of CCl4-treated rats (WEBER; BOLL; STAMPFL, 2003). In agreement with this, CCl4 significantly increased the level of hepatic TBARS (by 44%) of G2 in this study compared to the control group (G1). The A. crassiflora seed extract (G6) significantly decreased the levels of TBARS compared to CCl4-treated rats (~41%), as shown in Figure 1. The A. crassiflora peel (G3) and seed extracts (G4) alone inhibited TBARS formation by 22 and 27%, respectively, compared to the saline controls.

3.3 Influence of A. crassiflora seed and peel extracts on the hepatic content of cytochrome P450 and b5

The recognition of clinically significant interactions between plant-based drugs and conventional medicines has raised concerns regarding the potential of herbal products to interfere with the metabolism of medications such as kava-kava and echinacea (GORSKI et al., 2003; ZOU et al., 2004). However, as shown in this study (Figure 2), the extracts alone did not alter the basal levels of cytochrome P450. CCl4 decreased the content of cytochrome P450, and the A. crassiflora seed and peel extracts were unable to prevent this reduction. However,

Values are expressed as mean ± SD of 6-7 animals. (*) Represents relative changes in parameters assessed (i.e., levels of parameter assessed in livers of rats receiving test substance to that of control rats). (1) Represents significant difference from group 1 at p < 0.05; (2) represents significant difference from group 2 at p < 0.05; (3) represents significant difference from group 3 at p < 0.05; and (4) represents significant difference from group 4 at p < 0.05.
there was no additive effect in rats treated with the extracts and CCl₄ (Figure 2). On the other hand, both extracts induced cytochrome b5, even under CCl₄ effect.

3.4 Influence of A. crassiflora seed and peel extracts on hepatic catalase activity

Catalase converts H₂O₂ to water and oxygen and also converts hydroperoxides to the corresponding alcohols in the presence of a hydrogen donor (AEBI, 1984). As shown in Figure 3, a single dose of CCl₄ produced a reduction of catalase activity by 23% (G2). Both of the A. crassiflora extracts prevented the decrease in catalase activity caused by CCl₄ (G5 and G6).

3.5 Influence of Anona crassiflora seed and peel extracts on hepatic glutathione peroxidase (G-Px) and glutathione reductase (GRed) activities

Enzymes involved in the detoxification of ROS and lipid hydroperoxides include the glutathione redox cycling enzymes, glutathione peroxidase (GPx), and glutathione reductase (GRed). GPx catalyzes the inactivation of H₂O₂ and its activity is the greatest when the enzyme is in its reduced form. Other enzymes, notably catalase and glutathione-S-transferase, also influence the activity of GPx. While catalase competes with GPx for H₂O₂, glutathione-S-transferase competes with GPx only for hydroperoxides (YUAN; KITTS, 1996). In our study, there were no significant changes in the GPx and GRed activities among the different groups including the rats treated with CCl₄ (Figure 4), possibly because of competition with enzymes such as catalase.

3.6 Influence of A. crassiflora seed and peel extracts on the level of glutathione equivalents (GSH equivalents)

Under physiological conditions, GSH occurs in its reduced form with oxidation leading to the formation of glutathione disulfide (GSSG). There has been considerable interest in the redox state of GSH and GSSG (THEODORUS; SIES; AKERBOOM, 1981). In the rats, treatment with the peel extract increased the GSH levels, whereas the seed extract had no effect. CCl₄ significantly increased the level of GSH equivalents, and this increase was partially prevented by both A. crassiflora extracts (Figure 5). Since the oxidation of GSH in vivo can lead to the formation of GSSH and hydrogen peroxide, the...
Roesler

radical scavenging potential of Annona crassiflora peel and seed extracts at different concentrations by the DPPH method, and the seed and peel presented IC\textsubscript{50} of 31.14 and 48.82 µg.mL\textsuperscript{–1}, respectively.

The inhibition of lipid peroxidation using rat liver microsomes as an oxidative system was evaluated, and it was found that fifty percent inhibition of lipid peroxidation of microsomes to TBARS requires 1.72 µg.mL–1 of seed ethanolic extract, 4.44 µg.mL–1 of peel ethanolic extract, and 8.62 µg.mL–1 of pulp etanolic extract (ROESLER et al., 2006).

In the present study, an experimental model of acute hepatotoxicity in Wistar Rats was induced by oral administration of CCl\textsubscript{4}. CCl\textsubscript{4} has been extensively used in experimental models to elucidate the cellular mechanisms behind oxidative damage (BASU, 2003). CCl\textsubscript{4} is activated by cytochrome P450 (CYP) 2E1, 2B1/B2, and possibly 3A to form trichloromethyl radicals (CCl\textsubscript{3}•).

Figure 5. Hepatic glutathione (GSH) equivalents in rats treated with CCl\textsubscript{4} in the absence and presence of A. crassiflora seed and peel extracts. The columns represent the mean+S.E.M. of at least 5 rats. (1) represents significant difference from group 1 at p < 0.05; (2) represents significant difference from group 2 at p < 0.05; (3) represents significant difference from group 3 at p < 0.05, and (4) represents significant difference from group 4 at p < 0.05.

Figure 6. Hepatic SOD inhibition of autoxidation of epinephrine in rats treated with CCl4 in the absence and presence of A. crassiflora seed and peel extracts. The columns represent the mean+S.E.M. of at least 5 rats. (1) Represents significant difference from group 1 at p < 0.05 and (4) represents significant difference from group 4 at p < 0.05.

increased level of GSH equivalents caused by CCl\textsubscript{4} probably corresponded to GSSH.

3.7 Influence of A. crassiflora seed and peel extracts on hepatic SOD activity

The ability of superoxide dismutase to inhibit the autoxidation of epinephrine at pH 10.2 has been used as the basis of a convenient and sensitive assay for this enzyme. SOD was determined by measuring the inhibition of the adrenochrome formation rate (MISRA; FRIDOVICH, 1972) in the reaction medium containing 1mM-adrenaline (epinephrine) and 50 mM-glycine/NAOH, pH 9.6 (BOVERIS et al., 1983). The treatment with CCl\textsubscript{4} induced the autoxidation of epinephrine; therefore, the inhibition of autoxidation had a reduction of 34% compared with the control group. As shown in Figure 6, the two A. crassiflora extracts alone significantly decreased the SOD activity and consequently increased the autoxidation of the epinephrine. The A. crassiflora peel (G3) and seed (G4) inhibited the autoxidation of epinephrine by only 48.1 and 28.9%, respectively, while the control (G1) showed an inhibition of approximately 74%. The profile of SOD activity seen with the extracts was unaltered by concomitant treatment with CCl\textsubscript{4}.

4 Discussion

Araticum (A. crassiflora) is a tree that bears a typical fruit known as araticum of cerrado or cerradão. Its fruits are consumed extensively “in natura” but have no commercial value in Brazil. The seeds in oil are used against scalp infections and in the folk medicine. The leaves and seeds infusion is used against diarrhea and as antitumoral agent (LORENZI, 1988; ALMEIDA et al., 1994). Many members of annonaceae are used in folk medicine for antiparasitic or antitumoral treatment of intestinal diseases. Previous studies have shown the in vitro free radical scavenging potential of Annona crassiflora peel and seed extracts at different concentrations by the DPPH method, and the seed and peel presented IC\textsubscript{50} of 31.14 and 48.82 µg.mL\textsuperscript{–1}, respectively. The inhibition of lipid peroxidation using rat liver microsomes as an oxidative system was evaluated, and it was found that fifty percent inhibition of lipid peroxidation of microsomes to TBARS requires 1.72 µg.mL\textsuperscript{–1} of seed ethanolic extract, 4.44 µg.mL\textsuperscript{–1} of peel ethanolic extract, and 8.62 µg.mL\textsuperscript{–1} of pulp etanolic extract (ROESLER et al., 2006).

In the present study, an experimental model of acute hepatotoxicity in Wistar Rats was induced by oral administration of CCl\textsubscript{4}. CCl\textsubscript{4} has been extensively used in experimental models to elucidate the cellular mechanisms behind oxidative damage (BASU, 2003). CCl\textsubscript{4} is activated by cytochrome P450 (CYP) 2E1, 2B1/B2, and possibly 3A to form trichloromethyl radicals (CCl\textsubscript{3}•).
and trichloromethyl peroxy radicals (CCl₃OO*) that cause lipid peroxidation and subsequent tissue damage (WEBER; BOLL; STAMPFL, 2003). Enhanced lipid peroxidation associated with a depletion of tissue antioxidants is a characteristic of CCl₄-treated rats (SIPES; KRISHNA; GILLETTE, 1977).

Direct evidence of this hepatotoxicity was noted through alterations in hepatic parameters in the second group (G2), such an increase in hepatic lipid peroxidation (MDA concentration), decreased phase I cytochrome P450 content, decreased phase II CAT and SOD activity, and increased GSH-equivalent level. The present results agree with previously reported data (JAYAKUMAR; RAMESH; GERALDINE, 2006; SRINIVASAN et al., 2005; SINGAB et al., 2005; CHIDAMBARA MURTHY; JAYAPRAKASHA; SINGH, 2002; ZHU et al., 1999).

Since free radicals play an important role in CCl₄-induced hepatotoxicity, it seems logical that compounds that neutralize such radicals may have a hepatoprotective effect.

The oral administration of A. crassiflora peel (G3) and seed extract (G4) inhibited the TBARS formation by 22 and 27%, respectively. A. crassiflora seed extract (G6) significantly decreased the levels of TBARS compared with the CCl₄-treated group (G2) by 41%. Thus, the maintenance of normal levels of hepatic MDA in group 6 (administered A. crassiflora seed extract + CCl₄) is of great interest since it provides evidence to suggest a hepatoprotective effect. The lipid peroxidation control in vivo is important for several reasons, in particular because it contributes to the development of atherosclerosis. The products of lipid peroxidation, particularly the citotoxic aldehydes such as malondialdehyde (MDA), are important because they can also cause damage DNA (HALLIWELL; ARUOMA, 1960). Thus, the maintenance of normal levels of hepatic MDA is of great interest since MDA is a major aldehyde resulting from the peroxidation of biological tissue and it is an indicator of tissue damage. Lipid peroxidation may be prevented at the initiation stage by free radical scavengers, whereas the chain propagation reaction can be intercepted by peroxy-radical scavengers such as phenolic antioxidants (TAKAHAMA, 1983). The investigation by direct infusion electrospray ionization mass spectrometry (ESI-MS) provided important information of biactive components of araticum extracts mainly phenolic antioxidants such as caffeic acid, quinic acid, ferulic acid, xanthoxylin, caffeoyltartaric acid, caffeoyl glucose, [quercetin + hexose + pentose – H]⁺, and rutin (ROESLER et al., 2007). The phenolic compounds act by scavenging free radicals and quenching the lipid peroxides. The hydroxyl and phenoxy groups of phenolic compounds donate their electron to the free radicals and neutralize them forming phenolic radical and quinone methide intermediate, which is excreted via bile (PAN et al., 1999).

The consumption of vegetables and fruits is known to reduce the risk of cancer (WATTENBERG, 1992). In general, the induction of phase 2 drug-metabolizing enzymes, the suppression of phase 1 enzymes, or the combination of these actions have been reported to be the mechanisms responsible for the protection against toxic and neoplastic effects of carcinogens (TALALAY, 1989; 2000).

The phase 1 enzyme cytochrome P450 dependent monoxygenase system is responsible for the oxidative and reductive metabolism of a variety of drugs, carcinogens, pesticides, and steroid hormones. The monoxygenase system is subject to the inductive and inhibitory effects of environmental and genetic factors, which may play an important role in determining the biological fate of foreign chemicals that require P450-mediated detoxication or bioactivation. A. crassiflora extracts preserve the cytochrome P450 content which is comparable with the control values of the enzyme. The pre-treatment with the A. crassiflora extracts was unable to alleviate the inhibition of the cytochrome P450 activity of the CCl₄-treated group. On the other hand, both extracts induced cytochrome b5, even under CCl₄ effect. The role of this enzyme includes electron transfer, coupled catalysis, and allosteric regulation of cytochrome P450 during the metabolism of endogenous and xenobiotic compounds (PORTER, 2002). Cytochrome b5 is required in several reactions, such as fatty acids and hormones synthesis (SCHENKMAN; JANSSON, 2003). Shewita, El-Gabar and Bastawy (2001) described cytochrome b5 induction after concomitant administration of CCl₄ and antioxidants, but no changes were observed with single compound treatment. The mechanism of induction and the role of cytochrome b5 under CCl₄ and antioxidants exposure still requires further investigation.

Phase 2 enzymes play important roles in the detoxification of xenobiotics, and thus their up-regulation gives protection against potentially harmful insults from the environment (KONG et al., 2001). Living tissues are endowed with innate antioxidant defense mechanisms, such as the presence of the enzymes CAT, SOD, and GPx. A reduction in the activities of enzymes associated with the accumulation of highly reactive free radicals, leading to deleterious effects such as loss of integrity and function of cell membranes (REEDY; LOKESH, 1992; KRISHNAKANTHA; LOKESH, 1993; SHEELA; ANGUSTI, 1995). The administration of CCl₄ leads to the generation of a peroxyl radical, which is associated with the inactivation of CAT and SOD enzymes. This probably explains the significantly reduced activities of CAT and SOD in the rats challenged with CCl₄ (G2). The extracts of A. crassiflora are capable of enhancing/maintaining phase 2 enzymes’ activity. The only exception was observed for SOD phase 2 enzyme, whose activity was unexpectedly depleted by A. crassiflora extracts as much as for CCl₄.

Nutritional factors and dietary habits have a significant effect on the regulation of antioxidant enzyme activity. According to L’ Abbe, Trick and Beare-Rogers (1991), the SOD activity can be depleted in the liver and heart by fish oil diet. In addition, the decrease in the SOD activity in the heart has been already associated with weight loss (WOHALIEB; GODIN, 1978). As reported in Table 1, there was a significant difference between the body weight gain profile between the control group and the seed extract group (-23%). For the peel extract group, there was also a tendency for body gain profile reduction (-9%). In addition, araticum seeds have approximately 16% of lipids (ROESLER et al., 2006). The lipids from the seeds were not removed before preparing the extracts and the solvent used for the extraction process also removed lipids; therefore, it is possible to affirm that the seed extract has approximately 16% of lipids as well. The composition of araticum oil had already

Preventive effect of A. crassiflora on live rats
been reported by Zuppa (2001). It contains approximately 15% of saturated fatty acids (palmitic and stearic acids), 51% of monounsaturated fatty acid (oleic acid), and 32% of polyunsaturated fatty acid (linoleic and linolenic acids). Fish oil has approximately 32% of saturated fatty acids (miristic and palmitic acids), 25% of monounsaturated fatty acids (oleic and palmitoleic acids), and 40% of polyunsaturated fatty acids (20:5 n-3 and 22:6 n-3) (GAMBOA; GIOIELLI, 2006). The arachidonic acid has quantities of polyunsaturated fatty acid as high as those of fish oil, but fish oil has more fatty acids with long chain. Therefore, further studies are needed for better understanding of A. crassiflora seed and peel extracts, SOD activity, and nutrition and metabolic factors that can regulate antioxidant enzyme activity.

Glutathione is a major non-protein thiol present in living organisms and performs as a key role in coordinating antioxidant defense mechanisms. The main role of GSH (L-γ-glutamyl-L-cysteinyl-glycine) in vivo is to be a primary agent involved in deactivating electrophile free radicals. The oxidation of GSH as an antioxidant can occur in vivo with oxidized glutathione (GSSH) (YUAN; KITTS, 1996). Treatment with CCl4 induced the GSH-equivalents by 140%. Since the oxidation of GSH in vivo can lead to the formation of GSSH and hydrogen peroxide, the increased level of GSH equivalents caused by CCl4 probably corresponded to that of the GSSH. This increase in GSH-equivalents, probably GSSH, was partially prevented by both A. crassiflora extracts.

The treatment of rats with a single dose of CCl4 at 2.0 g kg−1 of body weight and the pre-treatment with the Annona crassiflora seed and peel extracts at 50 g kg−1 (in terms of gallic acid equivalents) were not able to alter significantly the level of glutathione peroxidase (G-Px) and glutathione reductase (G-red).

5 Conclusions

In conclusion, our results show that ethanolic extracts of A. crassiflora can enhance or maintain the activity of hepatic antioxidant enzymes, except for SOD, which was unexpectedly depleted by the extracts to a similar extent as that seen with CCl4. The pretreatment with A. crassiflora extracts protected against CCl4 toxicity, as shown mainly by the lipid peroxidation assay, catalase activity, and level of GSH equivalents. In contrast, the treatment with CCl4 and the pretreatment with A. crassiflora extracts did not significantly alter the level of glutathione peroxidase and glutathione reductase. It is also important to emphasize that the A. crassiflora extracts preserved the cytochrome P450 content which can be compared to the control values of the enzyme. Hence, there is probably no need to be concerned about interactions between plant-based drugs and conventional medicines. The antioxidant activity of the A. crassiflora extracts in vitro (ROESLER et al., 2006) and in vivo, as demonstrated in this study, may be mediated by compounds such as ascorbic acid, caffeic acid, quinic acid, ferulic acid, xanthohyxin, caffeoyltartaric acid, caffeoyl glucose, [quercetin + hexose + pentose-H], and rutin. These compounds are widely reported as potent antioxidants and can probably explain the antioxidant activity of the A. crassiflora extracts (GÜLÇİN, 2006; KIM et al., 2006; ROCHE et al., 2005; KWEON; HWANG; SUNG, 2001). The present study represents the first attempt in determining whether the Annona crassiflora extracts can protect Phase 1 and Phase 2 hepatic enzymes against CCL4 induced liver damage. Further studies are needed to elucidate the mechanisms involved in this hepatic protection and to explore possible synergism among the components of the extracts.
