COMISSÃO EXAMINADORA

Prof. Dr. Daniel Martins de Souza

Dra. Lucilene Delazari dos Santos

Prof. Dr. José Luiz Proença Modena

Os membros da Comissão Examinadora acima assinaram a Ata de Defesa, que se encontram no processo de vida acadêmica do aluno.

A Ata da defesa com as respectivas assinaturas dos membros encontra-se no SIGA/Sistema de Fluxo de Dissertação/Tese e na Secretaria do Programa de Pós Graduação em Biologia Funcional e Molecular da Unidade do Instituto de Biologia da Universidade Estadual de Campinas.

DEDICATÓRIA

Dedico essa dissertação aos meus pais, que sempre me apoiaram e me incentivaram. Também dedico essa dissertação ao meu namorado, Guilherme Serradilha Gonçalves, que me deu força e suporte nos momentos mais difíceis. Espero conseguir retribuir a todos tudo aquilo que vocês já fizeram e fazem por mim.

AGRADECIMENTOS

O presente trabalho foi realizado com apoio da Coordenação de Aperfeiçoamento de Pessoal de Nível Superior - Brasil (CAPES) - Código de Financiamento 001.

Agradeço o apoio financeiro da Fundação de Amparo à Pesquisa do Estado de São Paulo – FAPESP pelo apoio financeiro (Processo 2018/25439-9).

Ao meu orientador, prof. Dr. Daniel Martins de Souza, por toda orientação e oportunidades que me proporcionou ao longo do desenvolvimento dos 02 projetos de iniciação científica e do mestrado no Laboratório de Neuroproteômica (LNP). Sou extremamente grata por ter tido a oportunidade de fazer parte do time do LNP.

Aos meus colegas do Laboratório de Neuroproteômica, pela companhia e ajuda profissional. Agradeço em especial à Dra. Fernanda Crunfli pelas orientações em relação ao desenvolvimento dos experimentos, bem como no desenvolvimento do artigo de revisão que publicamos; à Dra. Valéria de Almeida por todo apoio científico ao longo do mestrado, por toda orientação e suporte. Val e Fer, vocês são minhas inspirações, exemplos incríveis de cientistas, profissionais. À Giuliana Zuccoli por toda ajuda, apoio e suporte desde os meus projetos de iniciação científica até os momentos finais do mestrado.

A todos, minha eterna gratidão, sem vocês nada disso seria possível.

RESUMO

Em 2015, o surto brasileiro do Zika vírus foi acompanhado por um aumento no número de casos de microcefalia, que envolve graves alterações no desenvolvimento cerebral, indicando uma possível associação da infecção viral com essas malformações cerebrais. Os mecanismos moleculares que promovem essas modificações ainda não se encontram totalmente elucidados. Assim, a investigação dos processos envolvendo o neurodesenvolvimento desencadeados pela infecção viral e as vias bioquímicas que ela afeta é de extrema importância. Para tanto, modelos de estudo utilizando células tronco de pluripotência induzida diferenciadas em células neurais podem ser empregados como modelo de neurodesenvolvimento. Neste trabalho, células tronco neurais foram infectadas com cepas de vírus Zika e Dengue. A infecção também foi realizada em neuroesferas, geradas a partir do cultivo em suspensão das células tronco neurais, visando analisar *in vitro* as modificações causadas pela infecção viral nesses modelos, que são um dos tipos celulares mais afetados pelo vírus Zika. As amostras, infectadas ou não com uma cepa dos diferentes vírus, foram submetidas à análise proteômica quantitativa em larga escala, com o objetivo de analisar diferenças e semelhanças em relação aos efeitos das cepas virais do Zika brasileiro e africano, bem como ao perfil molecular causado pela infecção do vírus da Dengue. A análise quantitativa do proteoma celular permitiu a identificação de diferenças em processos biológicos incluindo transporte celular, metabolismo de RNA e neurogênese, além de proteínas, como DCX, SEPHS1 e DYNC2H1, que podem estar relacionadas aos mecanismos e desenvolvimento da infecção viral em células neurais. Portanto, com este trabalho foi possível investigar potenciais distinções em relação às respostas celulares induzidas pela infecção com cepas de Zika e Dengue, proporcionando avanços em relação à compreensão das alterações celulares induzidas pelos flavivírus.

ABSTRACT

The Brazilian Zika virus outbreak in 2015 was accompanied by an increased in the number of cases of microcephaly, which involves severe changes in brain development, indicating a possible association between the viral infection with these brain malformations. The molecular mechanisms that promote these changes are not yet fully understood. Thus, investigating the processes involving neurodevelopment triggered by viral infection and the biochemical pathways it affects is extremely important. Therefore, models using induced pluripotent stem cells differentiated into neural cells can be used as a neurodevelopment model. Here, neural stem cells have been infected with strains of Zika and Dengue virus. The infection was also carried out in neurospheres, generated from the suspension culture of neural stem cells, to analyze *in vitro* the changes caused by viral infection in these models, which are one of the cell types most affected by the Zika virus. The samples, infected or not with a strain of the virus, were subjected to quantitative proteomic analysis on a large scale, with the aim of analyzing differences and similarities regarding the effects of the Brazilian and African viral strains, as well as comparing Zika virus infection with the Dengue. The quantitative analysis of the cellular proteome allowed the identification of biological processes, including altered cellular transport, RNA metabolism, and proteins, such as DCX, SEPHS1 and DYNC2H1, that may be related to the mechanisms and development of viral infection in neural cells. Thus, we were able to point out potential differences between the cellular response to the different strains of Zika virus and Dengue, gathering relevant information regarding the comprehension of the molecular mechanisms induced by flaviviruses.

ÍNDICE DE FIGURAS

CAPÍTULO I

Figure 1. The three different viral strains infected NSCs for two hours. Then, two different protocols were performed: the culture of NSCs for three days and the protocol for NSCs cultivated in suspension, as neurospheres, for three days. The cells were harvested and the samples were prepared for proteomic analysis, followed by *in silico* analysis.

Figure 2. Comparison of regulated proteins found in neural stem cells (NSC) and neurospheres infected by ZIKV (Br and MR766 strains) and DENV. A. Overlap of proteins differentially regulated in NSCs, represented by chord diagram lines in purple (ZIKV MR766 and DENV), green (Br ZIKV and DENV), pink (Br ZIKV and MR766) and black for commonly found in all three viral strains. Light gray lines on the background are relative to the overlap of pathways and GO terms enriched by regulated proteins in NSCs. B. Pearson correlation of the effects of ZIKV strains and DENV on NSCs. C. Overlap of proteins differentially regulated in neurospheres, represented by chord diagram lines in purple (ZIKV MR766 and DENV), green (Br ZIKV and DENV), pink (Br ZIKV and MR766) and black for commonly found in all three virus strains. Light gray lines on the background are relative to the overlap of pathways and GO terms enriched by regulated proteins in neurospheres. D. Pearson correlation of the effects of ZIKV strains and DENV on neurospheres.

Figure 3. Comparison of pathways and proteins associated with NSCs and neurospheres infected by ZIKV (Br and MR766 strains) and DENV. Heatmap hierarchical clustering of enriched ontology terms and pathways altered due to differentially regulated proteins in A. NSCs and B. neurospheres. C. Differential expression data of commonly deregulated proteins among the ZIKV MR766, Br ZIKV and DENV infections in NSCs and neurospheres.

Figure 4. Regulation of pathways enriched in NSCs and neurospheres infected by ZIKV (Br and MR766 strains) and DENV. Heatmap showing the regulation of enriched pathways in A. NSCs and B. neurospheres, where colors represent the median fold change of proteins within the pathway.

Figure 5. Protein-protein interaction network from the differentially regulated proteins infected by ZIKV in NSCs. A. Clustered interactions of proteins modulated by ZIKV MR766 in comparison to MOCK. In red, SRP-dependent cotranslational protein targeting the membrane ($\text{Log}_{10}(\text{P})$ -16.3) and ribosome activity ($\text{Log}_{10}(\text{P})$ -12.9). In blue, cytoplasmic

translational initiation (Log10(P) -6.3) and RNA transport (Log10(P) -6.0). In green, RNA splicing, via transesterification reactions with bulged adenosine as a nucleophile (Log10(P) -11.2), mRNA splicing, via spliceosome (Log10(P) -11.2). In purple, proton transmembrane transport (Log10(P) -6.1). **B.** Clustered interactions of proteins modulated by Br ZIKV in comparison to MOCK. The cluster in red represents the enrichment of biosynthesis of amino acids (Log10(P) -9.1) and glucose metabolism (Log10(P) -6.2); in green, mRNA splicing (Log10(P) - 6.6).

Figure 6. Protein-protein interaction network identified in the differentially regulated proteins infected by ZIKV in Neurospheres. **A.** Clustered interaction of proteins modulated by ZIKV MR766 in comparison to MOCK. The red cluster was enriched for L13a-mediated translational silencing of Ceruloplasmin expression (Log10(P) -25.3), eukaryotic translation initiation (Log10(P) -24.9) and Cap-dependent translation initiation (Log10(P) -24.9). The blue cluster was enriched for the role of GTSE1 in G2/M progression after G2 checkpoint (Log10(P) -22.0), separation of sister chromatids (Log10(P) -17.9) and G2/M transition (Log10(P) -17.9). The green one was enriched for RAB GEFs exchange GTP for GDP on RABs (Log10(P) -5.3). And the orange one for COPI-mediated anterograde transport Log10(P) -7.3, Golgi-to-ER retrograde transport (Log10(P) -7.0) and ER to Golgi Anterograde Transport (Log10(P) -6.8).

B. Clustered interaction of proteins modulated by Br ZIKV in comparison to MOCK. The cluster in red was enriched for the cellular amino acid metabolic process (Log10(P) -19), the role of GTSE1 in G2/M progression after G2 checkpoint (Log10(P) -17.6) and proteasome (Log10(P) -17.1). The cluster in blue was enriched for the HSP90 chaperone cycle for steroid hormone receptors (SHR) (Log10(P) -5.6), mitochondrial protein import (Log10(P) -5.4) and cellular responses to stress (Log10(P) -5.2). The cluster in green was enriched for SRP-dependent cotranslational protein targeting to the membrane (Log10(P) -16.6), influenza Viral RNA Transcription and Replication (Log10(P) -15.9) and influenza Infection (Log10(P) -15.4).

1 INTRODUÇÃO

1.1 Zika Vírus

O Zika vírus (ZIKV) é um arbovírus pertencente à família Flaviviridae, que compreende vírus causadores de doenças em humanos, incluindo o vírus da Dengue (DENV) e o da hepatite C. Em 1947, o ZIKV foi isolado a partir do sangue de macacos Rhesus infectados, havendo poucos indícios de infecções em humanos durante décadas desde o isolamento viral. O registro de novos casos de infecção em humanos ocorreu nos anos de 2013 e 2014, na Polinésia Francesa e em algumas ilhas do Pacífico (Dick et al., 1952; Fauci et al., 2016; Petersen et al., 2016).

Com a dispersão do vírus pela América, nos anos 2014 e 2015, houve uma alarmante mobilização, em função das severas alterações no desenvolvimento cerebral que foram então relacionadas com essa doença infecciosa (Gulland 2016). No Brasil, o surto do ZIKV foi acompanhado pelo aumento no número de casos de microcefalia em neonatos de mães infectadas pela cepa brasileira do Zika vírus, doença relacionada ao neurodesenvolvimento a qual o vírus foi associado como agente causador. Esta grave doença neurológica prejudica o neurodesenvolvimento, sendo que sua fisiopatologia se relaciona principalmente com alterações nos processos proliferativos das células progenitoras neurais e em processos migratórios durante o neurodesenvolvimento (Woods et al., 2005; Woods et al., 2013).

De acordo com a Organização Mundial da Saúde (OMS), a microcefalia caracteriza-se por um perímetro encefálico com desvios de 2 níveis abaixo do padrão da mediana para determinada idade e sexo, resultando em complicações neurológicas, como retardo no desenvolvimento, convulsões, bem como quadros de deficiência auditiva e visual (Miranda-Filho et al., 2016). Sendo assim, diversos estudos buscam compreender a relação entre a infecção do ZIKV e o desenvolvimento de alterações neurológicas e malformações cerebrais (Calvet et al., 2016; Bayer et al., 2016; Cugola et al., 2016; Garcez et al., 2016; Qian et al., 2016; Tang et al., 2016).

Atualmente, sabe-se que o ZIKV é capaz de promover alterações no sistema nervoso em função de sua capacidade de invadir o tecido neural e de sua neurovirulência, ou seja, é capaz de infectar e proliferar em células nervosas (Calvet et al., 2016). Sabe-se que células progenitoras neurais derivadas de células tronco de pluripotência induzida (iPSCs), quando

infectadas com o ZIKV, apresentam alterações no ciclo celular, desregulando-o, e são induzidas à morte celular (Cugola et al., 2016; Tang et al., 2016; Garcez et al., 2017). Cabe ressaltar que dentre os tipos de mortes celulares, a indução da apoptose mediado pela atividade da caspase 3 (Tang et al., 2016; Garcez et al., 2017). Estudos utilizando células progenitoras neurais derivadas de iPSCs, permitiram comparar como o vírus pode afetar esses tipos celulares, provindos de diferentes cepas do ZIKV circulante, asiático, africano ou brasileiro, assim como em comparação destes com o DENV em níveis de expressão gênica (Zhang et al., 2016).

Em recente estudo, o ZIKV circulante no Brasil foi avaliado em nível celular e molecular, comparando as alterações no transcriptoma e no proteoma de neuroesferas e organoides derivados de células tronco neurais (Garcez et al., 2017). O estudo mostra o início das alterações derivadas da infecção, bem como a indicação de instabilidade cromossômica e interrupção do programa neurogênico. Este estudo corrobora e complementa informações que haviam sido apontadas por outros trabalhos envolvendo análise do transcriptoma de células progenitoras neurais infectadas com ZIKV asiático e africano, promovendo alterações como o retardo da proliferação celular, levando à morte celular (Zhang et al., 2016).

Em relação às diferentes cepas do ZIKV circulante, foi observado que as linhagens africana e asiática promoveram alterações específicas nas células progenitoras infectadas. O ZIKV asiático provoca alterações em mecanismos de replicação e reparo de DNA, bem como genes relacionados a sinalização de IFN (Zhang et al., 2016). Já o ZIKV africano, apresentou genes alterados mais especificamente relacionadas como processo de divisão e ciclo celular (Zhang et al., 2016). Na análise da cepa circulante no Brasil, foram identificadas proteínas diferencialmente expressas relacionadas a replicação viral, a retenção do ciclo celular, como CDKN1A, a resposta ao estresse e danos e falhas no reparo de DNA (Garcez et al., 2017). Porém a comparação direta dos efeitos das linhagens do ZIKV africano e brasileiro não se encontra totalmente elucidada, havendo a necessidade de estudos analisando as diferenças moleculares entre os processos de infecção dessas cepas.

Em relação à infecção por ZIKV utilizando modelos *in vitro* 3D, foram observadas alterações morfológicas em neuroesferas e redução do crescimento em organoides cerebrais em comparação ao controle (MOCK), não sendo evidenciadas alterações morfológicas em neuroesferas infectadas pelo DENV (Cugola et al., 2016; Garcez et al., 2016). Tais dados evidenciam que as alterações no desenvolvimento cerebral se relacionam aos mecanismos de

atuação do ZIKV, não sendo alterações gerais causadas por vírus da família Flaviviridae (Garcez et al., 2016). Ademais, foi demonstrado que as diferenças temporais e geográficas do ZIKV podem alterar diferencialmente aspectos específicos no processo de infecção, modificando diferentes vias metabólicas. Sendo imprescindível a investigação dos distintos mecanismos moleculares envolvidos com a infecção de diferentes flavivírus, incluindo ZIKV e DENV.

1.2 Dengue Vírus

O Dengue vírus (DENV), como mencionado anteriormente, também se trata de um arbovírus pertencente à família Flaviviridae, havendo quatro sorotipos distintos (DENV 1–4) (Guzman et al., 2015). De acordo com a OMS, o DENV é endêmico em mais de centenas de países, sendo que sua incidência tem aumentado nos últimos 50 anos, constituindo um importante problema de saúde pública (WHO 2012).

A maioria dos indivíduos acometidos são assintomáticos, porém pode ocorrer o desenvolvimento de quadros clínicos mais severos incluindo hepatite e alterações neurológicas (Acevedo et al., 1982; Guzman et al., 2015). Sendo que infecções secundárias, principalmente em adultos, aumentam os riscos para o desenvolvimento de alterações de permeabilidade vascular, levando a graves sangramentos (Thu et al., 2012).

Investigando os mecanismos moleculares por trás das alterações induzidas por DENV, estudos revelaram a modulação de proteínas e vias metabólicas relacionadas com a cascata de coagulação, adesão celular, autofagia e metabolismo lipídico (Han et al., 2019; Heaton et al., 2010; Koraka et al., 2004). Em comparação com a infecção por ZIKV, células infectadas por DENV apresentaram maiores alterações no transcriptoma, predominando genes relacionados com processos inflamatórios (Zhang et al., 2016). Ademais, como mencionado no tópico anterior, neuroesferas infectadas por ZIKV apresentaram alterações morfológicas, já em DENV tais alterações não foram observadas (Cugola et al., 2016; Garcez et al., 2016).

Sendo assim, novos estudos focados nestas diferenças de infecção pelo ZIKV e DENV podem auxiliar na compreensão das alterações induzidas pelas infecções virais e no desenvolvimento de possíveis abordagens terapêuticas relacionadas com a infecção por ZIKV, e as conseqüentes malformações cerebrais desencadeadas, bem como em relação à DENV.

1.3 O estudo de células neurais *in vitro*

Nos anos 1990, células tronco neurais (NSCs) foram isoladas a partir do tecido cerebral de mamíferos, possibilitando a investigação de aspectos relacionados ao neurodesenvolvimento (Reynolds et al., 1992). Desde então, avanços significativos ocorreram em relação ao cultivo de células neurais, incluindo o desenvolvimento de células de pluripotência induzida (iPSCs) a partir da reprogramação de células somáticas (Takahashi et al., 2006; Takahashi et al., 2007).

Nesses modelos, células tronco embrionárias e/ou iPSCs são diferenciadas para linhagens celulares específicas, sendo capazes de representar diferentes regiões cerebrais, bem como sistemas neurais tridimensionais, que resultam em neuroesferas ou até em organóides cerebrais (Dang et al., 2016). Tais modelos estruturais 3D podem se diferenciar, constituindo estruturas complexas. Portanto, mesmo não contemplando todos os aspectos mecânicos e fisiológicos observados nos modelos *in vivo*, os modelos *in vitro* tridimensionais têm proporcionado importantes avanços na comunicação e na interação celular, contribuindo para o estudo dos mecanismos de doenças e aspectos essenciais do neurodesenvolvimento em humanos e outros mamíferos (Dang et al., 2016; Lancaster et al., 2013).

Diferentes estudos e pesquisas em modelos *in vivo*, bem como em modelos *in vitro*, como os que utilizam células progenitoras neurais e organóides, estão em desenvolvimento a fim de investigar os mecanismos do ZIKV responsáveis pelas alterações e malformações cerebrais, estudando também a relação da infecção viral com a microcefalia (Cugola et al., 2016; Martines et al., 2016).

Os modelos *in vitro* são estratégias reprodutíveis e capazes de englobar os complexos processos iniciais do neurodesenvolvimento, permitindo a análise e compreensão dos mecanismos de atuação do ZIKV, bem como as alterações provocadas nas células nervosas, que resultam em quadros graves de malformações, como a microcefalia (Dang et al., 2016; Garcez et al. 2016). Ademais, os modelos *in vitro* possibilitam a comparação entre o processo de infecção nas células progenitoras e nas estruturas 3D de neuroesferas e organóides cerebrais, uma vez que o ZIKV tem como alvo principal as células progenitoras (Garcez et al. 2017).

Com os modelos 2D de células progenitoras neurais é possível obter informações sobre a infecção direta de uma monocamada de cultura. Já os modelos estruturais 3D, neuroesferas e organoides cerebrais, constituem estruturas mais complexas, permitindo o estudo da infecção do tecido, bem como da comunicação celular e outros mecanismos durante o neurodesenvolvimento, em associação ao que é observado *in vivo*. Dessa forma, a investigação das alterações celulares induzidas pela infecção viral, associadas às análises moleculares de larga escala, como a técnica da proteômica, podem contribuir para a identificação dos principais processos celulares e vias metabólicas afetadas pelo processo de infecção do ZIKV.

1.4 Proteômica

A proteômica é a ciência que estuda o proteoma, o qual corresponde ao conjunto de proteínas expressas em um indivíduo, um tecido ou uma célula, em um dado momento e/ou condição fisiológica (mod. Wilkins et al., 1996). Análises proteômicas permitem a identificação de proteínas diferencialmente reguladas nas amostras estudadas, sendo possível identificar os processos biológicos associados a essas proteínas por análises *in silico* (Martins-de-Souza et al., 2011; Martins-de-Souza et al., 2015). Ademais, também possibilita a busca por proteínas que sirvam como possíveis candidatos a biomarcadores, que podem auxiliar no diagnóstico de doenças, bem como predição de resposta a tratamentos.

Inserida no contexto da era pós-genômica, a proteômica consiste em uma área de estudo capaz de fornecer informações que vão além do produto da expressão gênica, caracterizando um fenótipo. Dessa forma, com a identificação e quantificação de proteínas, engloba-se aspectos envolvidos na regulação da tradução, interações proteína-proteína, bem como modificações pós-traducionais. Atualmente, o método mais comumente utilizado consiste na combinação da cromatografia líquida (LC) com a espectrometria de massas (MS). Em geral, sistemas de LC-MS são empregados em estudos de *shotgun proteomics*, abordagem que se refere à análise de uma mistura complexa de proteínas. Geralmente, estudo de *shotgun proteomics* são do tipo *bottom-up proteomics*, no qual o proteoma de interesse é submetido a uma digestão proteolítica. Os produtos (peptídeos) são separados por LC e as frações diretamente injetadas no espectrômetro de massas (Yates 2013). A principal alternativa a esta estratégia, consiste no emprego de *top-down proteomics*, em que proteínas intactas são submetidas à análise proteômica, permitindo a identificação de proteoformas e de

modificações pós-traducionais (Scheffler 2014). *Shotgun proteomics* consiste em um método de análise proteômica não direcionada por hipótese, ou seja, sua aplicação está focada na cobertura total do proteoma, identificando e, eventualmente quantificando, de maneira relativa, milhares de proteínas. Outra possível abordagem consiste em *targeted proteomics*, a qual permite a identificação de alvos específicos, de maneira mais precisa e sensível (Gillette et al., 2013).

1.5 Espectrometria de Massas (MS)

A MS consiste em uma técnica com elevada precisão qualitativa e quantitativa, que identifica moléculas a partir de suas razões massa/carga (m/z). Para tanto, a etapa de ionização é essencial. Diferentes técnicas estão disponíveis, sendo as principais aplicadas à proteômica, a ionização e dessorção a laser auxiliada por matriz (Matrix Assisted Laser Desorption/Ionization, MALDI) e a ionização por *eletrospray* (ESI) (Karas et al., 1988; Fenn et al., 1989).

Após a ionização dos analitos, obtêm-se íons em estado gasoso, que são então separados de acordo com sua relação m/z . Tal processo de separação ocorre nos analisadores de massa, que utilizam energia elétrica estática ou dinâmica e campos magnéticos isolados ou combinados para a distinção e separação dos íons (Porter et al., 1981). Exemplos de analisadores amplamente utilizados na proteômica são quadrupolo (Q, quadrupole mass filters), TOF (time of flight mass analyzers) e Orbitrap. Nos analisadores quadrupolo, são utilizados campos elétricos oscilantes, estabilizando ou seletivamente desestabilizando os íons, o que permite sua separação de acordo com os seus valores de m/z (Hoffmann et al., 2007). Já nos analisadores TOF, a relação m/z de um íon é obtida a partir do seu tempo de “vôo” no vácuo através de um tubo (Andrews et al., 2011). Já o analisador Orbitrap consiste num *trap* no qual os íons se deslocam a partir de um campo eletrostático ao redor de um eletrodo central, movimentando-se em um complexo padrão espiral. A corrente dos íons aprisionados é detectada individualmente e convertida em um espectro de massa usando a transformada de Fourier do sinal de frequência (Scigelova et al., 2006).

Assim, um espectrômetro de massas apresenta uma fonte de ionização, um ou mais analisadores, e possui também um detector, responsável por detectar e amplificar a informação fornecida pelo analisador, havendo a conversão de feixes de íons em sinais elétricos, gerando espectros de massas (Porter et al., 1981). Ademais, o acoplamento da LC

ao espectrômetro de massas (LC-MS) permite uma eficiente separação de misturas complexas, como peptídeos, melhorando a sensibilidade analítica e ampliando a cobertura do proteoma (Pitt 2009).

Os conjuntos de dados gerados por LC-MS são extraídos por meio de diferentes ferramentas computacionais automatizadas. Para proteômica, algumas utilizadas são MASCOT®, MaxQuant (Cox et al., 2008), PLGS® e Progenesis®. Tais ferramentas realizam a comparação com um banco de dados de espectros teoricamente obtidos, que são gerados com base no genoma do organismo estudado, permitindo a identificação das proteínas obtidas experimentalmente.

1.5.1 Empregando a proteômica na compreensão da infecção por ZIKV

Em relação aos estudos com o ZIKV, a análise do proteoma possibilita uma comparação entre as células tronco neurais controle (MOCK) e as infectadas pelo ZIKV. Primeiramente, foram investigados os efeitos da cepa brasileira do ZIKV em neuroesferas infectadas (Garcez et al. 2017). Porém, muitas perguntas ainda estão sem resposta em relação aos efeitos da infecção de diferentes cepas do ZIKV e seus efeitos em células neurais. Assim como pouco foi estudado na comparação de proteínas diferencialmente expressas entre o ZIKV e outros vírus da família Flaviviridae, como o DENV (Garcez et al., 2016; Garcez et al. 2017). Para auxiliar na interpretação do proteoma em relação às alterações desencadeadas por essas infecções virais, pode-se empregar ferramentas de análise de biologia de sistemas, que possibilitam estudos em larga escala de um amplo volume de dados, gerando informações sobre processos biológicos associadas às proteínas diferencialmente reguladas (Sherman et al., 2017).

Diante do grande volume de dados oriundos de experimentos empregando técnicas de genômica e proteômica, a existência de ferramentas e programas, que utilizam algoritmos e a informação biológica acumulada até então, permite a análise e a interpretação desse grande volume de dados (Sherman et al., 2007). Dentre tais programas e ferramentas, podemos citar o STRING, Reactome Knowledgebase e DAVID - Functional Annotation Bioinformatics Microarray Analysis. Cada uma dessas ferramentas apresenta diferentes métodos de análise e sua utilização combinada permite uma melhor interpretação dos dados que se deseja analisar.

Em relação ao STRING, tal ferramenta permite estabelecer uma correlação entre genes situados próximos entre si no genoma e a funcionalidade das proteínas que os codificam. Diante disso, trata-se de uma ferramenta de pesquisa para instâncias recorrentes de genes vizinhos (Snel et al., 2000). Possibilita a busca e interpretação de padrões na organização do genoma, permitindo explorar associações funcionais de um gene em questão (Snel et al., 2000).

Já a ferramenta de análise DAVID - Functional Annotation Bioinformatics Microarray Analysis, utiliza o banco de dados do Biocarta, constituindo uma base integrativa de conhecimentos biológicos. Possibilita a interpretação das funções de listas de genes e proteínas, além de apresentar ferramentas capazes de relacionar e comparar os genes inseridos na lista, bem como gerar mapas e figuras das vias metabólicas que envolvem as proteínas que se deseja analisar (Huang et al., 2009). Além disso, possibilita uma referência cruzada entre identificadores de genes e proteínas, como o UniProt e NCBI, sendo uma ferramenta capaz de ampliar e integrar as informações dessas diferentes fontes, resultando em uma melhor compreensão das funções e associações para um determinado gene (Huang et al., 2009).

Outra ferramenta de análise é o Reactome Knowledgebase, que reúne informações sobre diversos processos celulares, como transdução de sinal, transporte celular, reparo de DNA, gerando mapas metabólicos. As vias geradas no Reactome são organizadas hierarquicamente, agrupando vias específicas e detalhadas, como tradução e modificações pós-traducionais. E também agrupando funções e aspectos mais amplos como metabolismo proteico, gerando uma via gráfica (Jassal et al., 2020).

2 OBJETIVOS

A presente dissertação teve como objetivo contribuir para a compreensão de mecanismos moleculares por trás das alterações induzidas por ZIKV em células neurais humanas em desenvolvimento, dada a potencial associação do ZIKV com o processo de microcefalia observado em neonatos de mães infectadas.

Para isso, realizamos análise proteômica em larga escala de células tronco neurais e neuroesferas infectadas com diferentes cepas do Zika vírus (ZIKV 766 e Br ZIKV) e do vírus dengue (DENV), investigando aspectos comparativos em ambos os modelos *in vitro* em resposta à infecção viral.

3 MATERIAIS E MÉTODOS

3.1 Cultivo e infecção das células tronco neurais

O cultivo das células tronco neurais (NSCs), bem como o cultivo de neuroesferas foi realizado em parceria com o grupo do Prof. Stevens K. Rehen no Instituto D'Or de Pesquisa e Ensino (IDOR) e Instituto de Ciências Biomédicas ICB-UFRJ. As células foram cultivadas em monocamadas, assim como foi realizado o cultivo em suspensão, possibilitando a formação das neuroesferas, como previamente descrito em Garcez et al. 2017. Estas células foram infectadas pelas cepas brasileiras (Br ZIKV- KU497555), africana (ZIKV MR766), e pelo vírus da dengue (DENV2). Para realizar a infecção, o ZIKV foi propagado em células Vero (ATCC #CCL-81), cultivadas com DMEM e 5% de soro fetal bovino¹⁴. Então, o vírus foi submetido à titulação e congelado em alíquotas, bem como o meio condicionado em células Vero, porém não contendo o vírus, constituindo a condição MOCK.

As células das linhagens CF1CL10, CF2CL2 e GM23679A foram infectadas com *Multiplicity of infection* (MOI) 0.025, sendo incubadas por 2h. Após esse processo, foi realizada a troca para o meio de cultivo de NSCs, que consiste em advanced DMEM/F12 e neurobasal (1:1), suplementado com o fator de indução neural, sendo mantidas em cultivo por 3 dias após a infecção, para então prosseguir com as análises¹⁴. As amostras já em tampão de lise (descrito a seguir) foram então encaminhadas para o Laboratório de Neuroproteômica (LNP) de acordo com o protocolo de preparo amostra para proteômica.

3.2 Preparo das Amostras para Análise proteômica

Após o processo de infecção, as células foram lavadas em PBS gelado, raspadas da placa de cultura e coletadas em um tubo. Em seguida, as células foram centrifugadas (200g por 5 min), o PBS removido e o tampão de lise RIPA (300 mM NaCl; 50mM Tris, pH 7.4; 0.5% Triton X-100), contendo cocktail de inibidores de proteases cCOMPLETE (Roche) foi adicionado. Após a lise por aproximadamente 30 min em gelo, as amostras foram mantidas congeladas a -80°C e transportadas para o Laboratório de Neuroproteômica. Para a realização das etapas de quantificação e digestão, foram centrifugadas a 10,000g por 10 min para separação dos debris. Finalizando o preparo e a extração das proteínas das amostras. Assim, as proteínas obtidas no processo de extração foram quantificadas por fluorescência no Qubit®3.0 Fluorometer (Thermo Fisher Scientific), e 50µg de proteína de cada amostra foi submetida ao protocolo de digestão em gel de poliacrilamida SDS-PAGE. C As amostras foram

reduzidas com 100 mM de DTT (30 min a 60°C) e alquiladas com 200 mM de iodoacetamida (30 min à temperatura ambiente). Finalmente, as amostras foram digeridas a uma razão de 1:100 (tripsina: proteína m/m), em tampão e temperaturas ótimos (50 mM bicarbonato de amônio, a 37 °C) por 16h. As amostras foram mantidas congeladas (-20°C a -80°C) até a realização da análise de espectrometria de massas.

3.3 Análise proteômica

Foram injetados 500 pg/μL de peptídeos resultantes da digestão das proteínas, em um sistema nano-LC (ACQUITY UPLC (2D-RP/RP), que está acoplado ao espectrômetro de massas com fonte ionizadora nano-electrospray (ESI) instalada em um Synapt G2-Si (Waters). Na cromatografia líquida HSS T3 Column (1.8μm, 75μm×150 mm; Waters Corporation, USA), a eluição se deu com um gradiente de acetonitrila de 7% a 40% (v/v) por 95 minutos a uma taxa de fluxo de 0,4μL/min diretamente no Synapt G2-Si. Havendo a eluição dos peptídeos, que foram analisados online em ESI-MS e ESI-MS/MS em modo positivo. Os espectros de fragmentação (modo MS/MS) foram obtidos através do modo independente de coleta de dados (data independent analysis - DIA), mais especificamente com a otimização das energias de colisão dos precursores iônicos através de seus drift-time (UDMSE, Waters Co.). Tal método apresenta elevada eficiência na fragmentação dos peptídeos, havendo a fragmentação dos íons precursores, independentemente de seu pico de intensidade, obtendo um espectro mais complexo, porém favorecendo a identificação das proteínas (Cassoli, et al.2017). Os espectros foram deconvoluídos através do algoritmo Ion Accounting pelo Progenesis QI for Proteomics 3.0 (Waters Co.).

Para a atribuição dos espectros, utilizamos o banco de dados Homo sapiens do Uniprot (revisado, Outubro de 2019), com 1%de taxa de falsa descoberta (FDR), 2 fragmentos/peptídeo, 5 fragmentos/proteína,1 peptídeo/proteína. Como método de quantificação, utilizamos os 3 peptídeos mais intensos de cada proteína (High-3). Finalmente, os peptídeos com erro de massa maior de 20 ppm foram descartados, juntamente com eventuais proteínas contaminantes inerentes da prática de proteômica (ex.queratina).

Keywords neurodevelopment, microcephaly, Flaviviridae.

Abstract

The Brazilian Zika virus outbreak in 2015 was accompanied by an increased in the number of cases of microcephaly, which involves severe changes in brain development, indicating a possible association between the viral infection with these brain malformations. The molecular mechanisms that promote these changes are not yet fully understood. Thus, investigating the processes involving neurodevelopment triggered by viral infection and the biochemical pathways it affects is extremely important. Therefore, models using induced pluripotent stem cells differentiated into neural cells can be used as a neurodevelopment model. Here, neural stem cells have been infected with strains of Zika and Dengue virus. The infection was also carried out in neurospheres, generated from the suspension culture of neural stem cells, to analyze *in vitro* the changes caused by viral infection in these models, which are one of the cell types most affected by the Zika virus. The samples, infected or not with a strain of the virus, were subjected to quantitative proteomic analysis on a large scale, with the aim of analyzing differences and similarities regarding the effects of the Brazilian and African viral strains, as well as comparing Zika virus infection with the Dengue. The quantitative analysis of the cellular proteome allowed the identification of biological processes, including altered cellular transport, RNA metabolism, and proteins, such as DCX, SEPHS1 and DYNC2H1, that may be related to the mechanisms and development of viral infection in neural cells. Thus, we were able to point out potential differences between the cellular response to the different strains of Zika virus and Dengue, gathering relevant information regarding the comprehension of the molecular mechanisms induced by flaviviruses.

Introduction

The Zika virus (ZIKV) outbreak in 2015, which in Brazil and other American countries peaked in 2016, was an international concern due to the increased number of cases of congenital brain abnormalities such as microcephaly ('WHO | Zika epidemiology update', 2019). Microcephaly is a developmental disease and the virus is considered to be a causative agent (Bayer *et al.*, 2016; Calvet *et al.*, 2016; 'WHO | Zika epidemiology update', 2019); it severely impairs neurodevelopment and its virus-independent pathophysiology is mainly related to changes in the proliferative processes of neural progenitor cells (NPCs) and migratory processes during neurodevelopment (Woods *et al.*, 2005; Woods and Parker, 2013). This results in neurological complications, such as delayed development, seizures, as well as hearing and visual impairment (Miranda-Filho *et al.*, 2016). Therefore, several studies sought to understand the relationship between ZIKV infection and the development of neurological changes and brain malformations using animal models, human neurospheres and brain organoids (Cugola *et al.*, 2016; Dang *et al.*, 2016; Garcez *et al.*, 2016; Li *et al.*, 2016; Qian *et al.*, 2016; Tang *et al.*, 2016; Ledur *et al.*, 2020).

Previous studies have used pluripotent stem cell models to understand mechanistic effects of ZIKV on neurodevelopment, which includes deregulation of cell cycle and proliferation, oxidative damage and neural cell death (Cugola *et al.*, 2016; Tang *et al.*, 2016; Garcez *et al.*, 2017; Ledur *et al.*, 2020). In these models, pluripotent stem cells differentiated into 2D or 3D neural systems to represent different brain regions (Dang *et al.*, 2016). While 2D models of neural stem cells provide insight into the direct infection of a culture monolayer, 3D structural models, neurospheres and brain organoids, constitute more complex structures, allowing the study of tissue infection and essential cell communication and other mechanisms during neurodevelopment, closer to that which is observed *in vivo* (Lancaster *et al.*, 2013; Dang *et al.*, 2016; Garcez *et al.*, 2017). ZIKV-infected neurospheres revealed impaired growth and disrupted pathways, affecting neurogenesis during brain development (Garcez *et al.* 2017; Garcez *et al.* 2016).

Two major family strains of the Zika virus, the African and the Asian, are distinguished by sequencing analysis. Those found circulating in Brazil were matched to the Asian strains (Calvet *et al.*, 2016). Comparisons between African and Asian ZIKV strains have shown specific, unique changes in infected neural progenitors. While the African ZIKV strain induced gene alterations leading to impairments related to the cell cycle and cell death (Garcez *et al.*, 2016; Zhang *et al.*, 2016), the Asian ZIKV strains, including those circulating in Brazil, are connected to changes in oxidative stress, DNA replication and repair

mechanisms, chromosome instability and interruption of the neurogenic program, additionally affecting genes related to IFN signaling (Zhang *et al.*, 2016; Garcez *et al.*, 2017; Ledur *et al.*, 2020). Moreover, it has been reported that the Brazilian strain can induce a delayed innate immune response unlike the African and other Asian strains (Esser-Nobis *et al.*, 2019).

The more the temporal and geographical differences of ZIKV strains are studied, the more is understood about how specific aspects of the infection process can be altered by modifying different metabolic pathways. Nonetheless, the molecular mechanisms behind such differences remain largely unexplored. Here we investigated the molecular responses to two ZIKV strains (Br and MR766) in iPS-derived neural stem cells and neurospheres using label-free, mass-spectrometry based proteomics, and compared them to another mosquito-borne flavivirus, a Dengue virus strain. Here, we observe altered patterns of expression when comparing both ZIKV strains and DENV, with the modulation of pathways involved with cellular transport, glucose metabolism, neurogenesis, mRNA metabolism. Thus, molecular differences between the infection processes of these strains were focused on gathering data for the discovery of potential biomarkers, as well as to help understand and treat brain malformations triggered by the viral infection.

Methods

2.1 Ethics Statement

The experimental protocols and procedures were carried out in partnership with the Rehen Lab at the D'Or Institute for Research and Education (IDOR) and the Institute of Biomedical Sciences ICB-UFRJ. The experimental procedures were approved by the Institutional Research Ethics Committee of Hospital Copa D'Or (CEPCOPADOR) under protocols #727.269 and #1.269.816. All experiments were performed following relevant guidelines and regulations.

2.2 Culture of neural stem cells and neurospheres

Three different control iPS cell lines (CF1CL10, CF2CL2, and GM23679A) were differentiated into neural stem cells (NSC) using PSC neural induction medium (Thermo Fisher Scientific, USA), containing Neurobasal medium and PSC supplement, according to the manufacturer's protocol, and as previously described in (Garcez *et al.*, 2017). NSCs were

cultured in monolayers on neural induction medium (Advanced DMEM/F12 and Neurobasal medium (1:1), supplemented with PSC supplement, Thermo Fisher Scientific, USA), and media was changed every other day, and maintained at 37 °C in humidified air with 5% CO₂. Neurospheres were differentiated from NSCs cultured until 80% confluence and split with Accutase (Merck-Millipore, Germany). Resuspended cells were then grown under a 90 rpm rotation on Advanced DMEM/F12 and Neurobasal medium (1:1), supplemented with 1x N2 and 1x B27 supplements (Thermo Fisher Scientific, USA), and maintained at 37 °C in humidified air with 5% CO₂.

2.3 NSC infection with ZIKV and DENV

DENV (DENV2 16681) and ZIKV (BrZIKV (KU497555) and MR766) strains were propagated in C6/36 or Vero (ATCC #CCL-81) cells, respectively. Briefly, cells were cultured in mock or virus-infected medium supplemented with 2% FBS, collected, titred, and frozen in aliquots, as previously described in (Garcez *et al.*, 2016, 2017). NSCs were then infected with 0.025 MOI ZIKV (Br or MR766) or DENV2. After incubation for 2 hours, the medium was replaced with advanced DMEM/F12 and neurobasal media (1:1), supplemented with PSC supplement in NSCs, or suspended and cultured according to the neurosphere protocol. Cells were then maintained in culture for 3 days after infection, the same for both monoculture and suspended culture, enabling the formation of neurospheres.

Figure 1. The three different viral strains infected NSCs for two hours. Then, two different protocols were performed: the culture of NSCs for three days and the protocol for NSCs cultivated in suspension, as neurospheres, for three days. The cells were harvested, and the samples were prepared for proteomic analysis, followed by *in silico* analysis.

2.4 Protein Extraction and Digestion

After viral infection and incubation, cells were washed with ice-cold PBS, scraped, and collected into a tube. Then, cells were centrifuged (200xg for 5 min), and PBS was removed and fresh RIPA lysis buffer (300 mM NaCl; 50 mM Tris, pH 7.4; 0.5% Triton X-100) containing cOMPLETE protease inhibitor cocktail (Roche) was added. After lysis for approximately 30 min on ice, samples were kept frozen at -80°C.

Just prior to the quantification and digestion steps, cells were thawed and centrifuged at 10,000xg for 10 min to separate debris. The proteins obtained during the extraction were quantified by fluorescence in a Qubit® 3.0 Fluorometer (Thermo Fisher Scientific), and 50 µg of protein from each sample was submitted to SDS-PAGE polyacrylamide gel digestion (Shevchenko *et al.*, 2006). Briefly, SDS-gel slices containing protein samples were reduced with 100 mM DTT (30 min at 60 °C) and alkylated with 200 mM iodoacetamide (30 min at room temperature). Finally, the samples were digested at a ratio of 1:100 (trypsin:protein w/w), in Ambic buffer and optimal temperatures (50 mM ammonium bicarbonate, at 37°C) for 16h. Extracted peptides were kept frozen (-20°C to -80°C) until mass spectrometry analyses were carried out.

2.5 Proteomic Analysis

Peptide loads (500 pg/µL) were injected into a nano-LC system (ACQUITY UPLC; 2D-RP/RP) coupled to the mass spectrometer (Synapt G2-Si, Waters Corporation), ionized with with a nano-electrospray ionization source in positive mode (ESI+). Chromatographic separation was performed on a HSS T3 Column (1.8 µm, 75 µm × 150 mm, Waters Corporation, USA), eluted with an acetonitrile gradient from 7% to 40% (v/v) for 95 min at a flow rate of 0.4 µL/min directly into a Synapt G2-Si. The fragmentation spectra (MS/MS mode) were obtained through data-independent acquisition (DIA), with the optimization of collision energies of ionic precursors across their drift-time (UDMS^E, Waters Co.). This method results in a more complex spectrum but favoring the identification of proteins, with high efficiency in the fragmentation of peptide precursor ions, regardless of peak intensity (Cassoli *et al.* 2017). The mass spectrometer operated in resolution mode with an m/z resolving power of about 40 000 FWHM, using ion mobility with a cross-section resolving power at least $40 \Omega / \Delta\Omega$. Injection was performed by nano-electrospray ionization in positive ion mode nanoESI (+) and a NanoLock Spray (Waters, UK) ionization source. The lock mass channel was sampled every 30 sec. The MS/MS spectrum of [Glu1]-Fibrinopeptide B human

(Glu-Fib) from the NanoLock Spray source was used for calibration of the mass spectrometer. Biological samples were run in triplicates.

The spectra were deconvolved using the Ion Accounting algorithm by Progenesis QI for Proteomics version 3.0 (Waters Co.). For the assignment of spectra, we used the *Homo sapiens* database from Uniprot (revised, October 2019), and identified and quantified proteins using the following parameters: 1% false discovery rate (FDR), 2 fragments/peptide, 5 fragments/protein, and 1 peptide/protein. The 3 most intense peptides of each protein were used for relative quantitation (Hi-3). Finally, peptides with a mass error greater than 20 ppm were discarded, along with any contaminating proteins common in shotgun proteomics (e.g. keratin). Proteins were considered to be differentially expressed when one-way analysis of variance (ANOVA) returned a p-value < 0.05.

2.6 *In Silico* Analysis

Protein data were then submitted to bioinformatic analysis using tools, databases, and predictions in systems biology for *in silico* evaluation of protein interactions and altered metabolic pathways, including Metascape (Zhou *et al.*, 2019). The protein-protein interaction enrichment analysis was performed using the Molecular Complex Detection (MCODE) algorithm to identify network components and connections (Bader and Hogue, 2003). All the Metascape analyses were carried out with the update of 2020-09-16.

Other bioinformatic tools and databases include String (Szklarczyk *et al.*, 2018), Reactome Knowledgebase (Jassal *et al.*, 2019), CORUM (Giurgiu *et al.*, 2019), and the KEGG and KO (KEGG ORTHOLOGY) Databases (Kanehisa *et al.*, 2016).

Results and Discussion

NSCs and neurospheres are two different steps in cell organization and differentiation. Using those human iPSC-derived brain cells in different stages, we could explore and compare different molecular aspects of ZIKVs and DENV infection. While NSCs, which are one of the main targets of ZIKV (Tang *et al.*, 2016), are cultured and infected in monolayers, neurospheres are the 3D-derivations of those infected NSCs which were allowed to differentiate further due to cell-cell contact communication. Thus, the proteomic analyses of those NSCs and neurospheres by ZIKV and DENV resulted in a total of 792 differentially regulated proteins (p value < 0.05).

The whole-cell proteomic analyses of NSCs identified and quantified a total of 1265 proteins (Supplementary Table 1), of which 149 were differentially regulated (p value < 0.05) in ZIKV MR766, 53 in Br ZIKV and 121 in DENV, a combined modulation of 323 different proteins, as shown in Figure 2A. A comparative analysis of those proteins revealed 10 proteins in common between Br ZIKV and MR766, 7 between Br ZIKV and DENV and 28 between MR766 and DENV (Figure 2A), and several biological pathways are shared among the viruses. A Pearson correlation of total protein changes in NSCs shows differences of ZIKV strains in comparison to DENV. While Br ZIKV has a higher correlation with ZIKV MR766 (0.33) (Figure 2B) than DENV (0.04), ZIKV MR766 has a similar correlation between Br ZIKV and DENV (0.33 and 0.39, respectively).

As neural stem cells differentiated into neurospheres, we observed a shift in the effects of the viruses on neural cell proteomes. In neurospheres, we identified and quantified a total of 1068 proteins (Supplementary Table 2), 127 of which were differentially regulated (p value < 0.05) in ZIKV MR766, 182 in Br ZIKV and 160 in DENV. Analysis of proteins common among different strains revealed that Br ZIKV had 25 proteins in common with ZIKV MR766 and 34 in common with DENV, while DENV and ZIKV MR766 had 25 other proteins in common, with a total of 469 differentially regulated proteins in comparison to mock-treated cells (Figure 2C). Despite having few proteins in common, several pathways are shared. In contrast with NSCs, the correlation between both ZIKV strains was higher (0.65) than those with DENV, with a correlation of 0.33 for Br ZIKV and 0.18 for ZIKV MR766 (Figure 2D). Given that neurospheres represent later neurodevelopmental and organizational stages than NSCs, the proteomic differences observed may reflect the complexity of the models that can be affected by these viruses.

The proteomic data thus revealed that ZIKV strains, though similar in some regards, have a distinct signature that can change in response to neurodevelopmental cell conditions. The similarities and differences observed among the strains -- comparing the two ZIKV strains as well as ZIKV vs. DENV -- will be further explored in the following sections.

Figure 2. Comparison of regulated proteins found in neural stem cells (NSC) and neurospheres infected by ZIKV (Br and MR766 strains) and DENV. **A.** Overlap of proteins differentially regulated in NSCs, represented by chord diagram lines in purple (ZIKV MR766 and DENV), green (Br ZIKV and DENV), pink (Br ZIKV and MR766) and black for commonly found in all three viral strains. Light gray lines on the background are relative to the overlap of pathways and GO terms enriched by regulated proteins in NSCs. **B.** Pearson correlation of the effects of ZIKV strains and DENV on NSCs. **C.** Overlap of proteins differentially regulated in neurospheres, represented by chord diagram lines in purple (ZIKV MR766 and DENV), green (Br ZIKV and DENV), pink (Br ZIKV and MR766) and black for commonly found in all three virus strains. Light gray lines on the background are relative to the overlap of pathways and GO terms enriched by regulated

proteins in neurospheres. **D.** Pearson correlation of the effects of ZIKV strains and DENV on neurospheres.

3.1 ZIKV hijacks multiple pathways of cellular maintenance in NSCs and neurospheres

When exploring how different ZIKV virus strains can target neural cells and what some of their phenotypic consequences might be (Qian *et al.*, 2016; Gabriel *et al.*, 2017; Esser-Nobis *et al.*, 2019), several of the molecular dysregulations were varied among different models, strains and cell types. Previous indications that Br ZIKV effects could deplete neural stem cells (Garcez *et al.*, 2017) left unanswered questions regarding when the molecular effects of infections leading to major phenotypic changes first appear: in neural progenitor cells, or when those cells start to differentiate. Therefore, we looked deeper into the modulation occurring in neural cells by exploring affected proteins and pathways.

We identified a series of pathways enriched in both NSCs and neurospheres which revealed that a major target effect of ZIKV MR766 and Br ZIKV is to hijack the cellular machinery to perform viral transcription and replication. Beginning at the NSC stage, mRNA splicing, metabolism of RNA, nuclear transport, RNA degradation, protein folding, translation, protein processing in the endoplasmic reticulum (ER) and destabilizing microtubule-based movement are pathways constituting the main targets of ZIKVs (Figures 3A). These effects are essential for cell proliferation and growth and dysregulation culminates in cell cycle arrest of progenitor cells (Qian *et al.*, 2016; Tang *et al.*, 2016; Garcez *et al.*, 2017). During the neurosphere differentiation process, defects in cellular maintenance are enhanced, leading to a major cellular response to stress, including mitochondrial permeabilization, apoptosis and DNA change and repair, among other pathways (Figure 3B).

Figure 3. Comparison of pathways and proteins associated with NSCs and neurospheres infected by ZIKV (Br and MR766 strains) and DENV. Heatmap hierarchical clustering of enriched ontology terms and pathways altered due to differentially regulated proteins in **A**. NSCs and **B**. neurospheres. **C**. Differential expression data of commonly deregulated proteins among the ZIKV MR766, Br ZIKV and DENV infections in NSCs and neurospheres.

Although ZIKV and DENV infections shared several pathways, there were few differentially regulated proteins common to all three treatments. In NSCs, the only protein in common was cytoplasmic dynein 2, heavy chain 1 (DYNC2H1) (Figure 3C), a cellular motor protein with ATP binding activity that plays an important role in cell transport and division. DYNC2H1 showed consistent, downregulated expression in all viral strains compared to MOCK infected cells. DYNC2H1 variants have been associated with a lethal perinatal skeletal disorder (Chen et al., 2016) and a congenital malformation known as hypothalamic hamartoma (Fujita et al., 2019). Hence, those studies are in line with the association between DYNC2H1 and fetal malformations as a possible role in brain abnormalities induced by the Flaviviridae viruses, such as the congenital malformations, including microcephaly, caused by ZIKV (Calvet *et*

al., 2016; Cugola *et al.*, 2016), and neurological alterations linked to DENV (reviewed in Li *et al.*, 2017)

Regarding the neurospheres, 7 proteins were differentially regulated in both ZIKVs and DENV (Figure 3C), all of which showed a similar regulation in response to the viruses. Downregulated proteins were eukaryotic initiation factor 4A-II (EIF4A2), ribosomal protein L30 (RPL30), mostly when related to RNA metabolism, and 14-3-3 protein beta/alpha (YWHAB), ATP synthase peripheral stalk-membrane subunit B (ATP5PB), Reticulocalbin-1 (RCN1), and serine/threonine-protein phosphatase 2A (PPP2R2D), involved in ATP synthesis, cell signaling, and proliferation. These proteins are associated with the Hippo signaling pathway, which promotes the inactivation of YAP/TAZ transcription factors modulating the expression of genes related to cell growth, proliferation and apoptosis (Buttitta and Edgar, 2007). Previous studies have already linked ZIKV infection to the Hippo signaling (Garcia *et al.*, 2020), specifically regarding the control of cell proliferation, responses to stress, differentiation and renewal of stem cells in development and the apoptosis signaling pathway (Mo, Park and Guan, 2014). In contrast, the only protein that was found to be upregulated in all strains was glycylpeptide N-tetradecanoyltransferase 1 (NMT1; also known as N-myristoyltransferase 1), as shown in Figure 3C. NMT1 is a protein that performs N-terminal protein modifications (Rajala *et al.*, 2000) and is thought to be associated with mechanisms affecting viral replication of flaviviruses, as its inhibition impaired DENV replication (Suwanmanee *et al.*, 2019).

Although modulation of viral replication cellular machinery was present in ZIKVs and DENV, the direction of modulation diverged among the viruses. Our results revealed increased levels of FANCA (FA Complementation Group A) in ZIKV MR766-infected NSCs (Figure 3C), indicating a possible association between this strain and DNA damage, as FANCA activation is associated with the blockade of replication due to DNA damage (Deans and West, 2011). In Br ZIKV, however, this protein was observed downregulated. Downregulation of FA Complementation Group proteins have been associated with ZIKV infection, as a mechanism involved with viral replication and selective autophagy (Tiwari *et al.*, 2020).

In NSCs, the neuronal migration protein doublecortin, encoded by the gene DCX, was identified as downregulated in both ZIKV strains. This microtubule-associated protein is a key player in neuronal differentiation and migration (Gleeson *et al.*, 1999) and its downregulation, in both ZIKV MR766 and Br ZIKV, supports the evidence that these strains impact neurogenesis (Tang *et al.*, 2016; Gabriel *et al.*, 2017). DCX has been previously linked

to ZIKV infection and was also reported downregulated in transcriptomic and proteomic analyses of NPCs (Jiang *et al.*, 2018). This shows that ZIKV infection is able to disrupt and reorganize signaling regulation throughout the infected cell.

In neurospheres, the main divergent protein between the two ZIKV strains is already known to be essential for viral replication and intracellular transport of viruses. WASHC2C (WASH Complex Subunit 2C) (Figure 3C) is associated with the endolysosomal system, lysosomal degradation and receptor recycling (Bartuzi *et al.*, 2016; Hashimoto *et al.*, 2020) and was strongly downregulated in both ZIKV strains. WASH-depleted cells have been shown to display a collapsed endolysosomal system (Gomez *et al.*, 2012). Modifications in the aforementioned pathways suggest impaired cellular trafficking, affecting viral replication (Hashimoto *et al.*, 2020). Potentially aiming to escape from these host-cell mechanisms, the ZIKV-induced downregulation of WASHC2C might be associated with assured viral replication. These changes in turn deplete progenitors and disrupt the neuronal differentiation program due to interference in important pathways in NSCs and neurospheres by ZIKV infection.

3.2 The divergent modulation of pathways by ZIKV strains

ZIKV and DENV have shown distinct alterations on NSCs and neurospheres. ZIKV MR766 and DENV revealed a common modulated pattern of downregulated pathways in NSCs, whereas Br ZIKV revealed upregulated pathways (Figure 4A). This pattern, however, was not observed in neurospheres, where Br ZIKV was found to downregulate several pathways similarly to ZIKV MR766 and DENV in this 3D model (Figure 4B).

Despite being common to the three viruses, proteins involved in mRNA processes were, on average, upregulated in Br ZIKV infection of NSCs (Figure 4A); though DENV and ZIKV MR766 had major downregulation of proteins in this pathway. Another interesting aspect is the regulation of mRNA splicing, which was found upregulated in both ZIKV strains in NSCs and downregulated in DENV. However, in neurospheres, mRNA splicing was found upregulated in DENV (Figure 4A), indicating potential differences due to the distinct complexity of the models evaluated.

In addition to the previously mentioned dynein subunit DYNC2H1, in regards to cellular transport-related pathways, we also highlight biological processes of retrograde vesicle-mediated transport, Golgi to ER transport and Golgi organization, which might signal altered

protein conformation from the ER and have been observed in the ZIKV strains in NSCs and neurospheres. Moreover, NSCs showed downregulation of Ras-related protein Rab-6A (RAB6A) and RAB6B which are involved with cellular transport and secretory and endocytic pathways (Martinez and Goud, 1998) and RAB6B also plays a role in retrograde transport in neuronal cells (Wanschers *et al.*, 2007). RAB GTPases have been linked with viral replication mechanisms, especially within the late stages of viral replication (Spearman, 2018)

NSCs showed an upregulation of Ras-related protein Rap-1B (RAP1B), which exhibits GTPase activity (Scrima *et al.*, 2008) and is involved in biological processes such as the interleukin-12-mediated signaling pathway, neutrophil degranulation and negative regulation of synaptic vesicle exocytosis. Furthermore, RAP1B variants have been associated with congenital malformations (Niemann *et al.*, 2020). This might indicate a potential association involving ZIKV-induced altered expression of Ras GTPase and the development of congenital malformations.

Also regarding cellular transport alterations in NSCs, AKAP9 was found upregulated in ZIKV MR766 and downregulated in Br ZIKV (Supplementary Table 1), suggesting the existence of different mechanisms involving cellular transport in these viral strains. AKAP9 is a protein from the family of A-kinase anchor proteins (AKAPs), which are known for binding to the regulatory subunit of protein kinase A (PKA), arresting the holoenzyme to determined locations within the cell (Colledge and Scott, 1999). This gene encodes for proteins localized to the centrosome and the Golgi apparatus and its products interact with various signaling molecules from multiple signal transduction pathways (Witczak *et al.*, 1999; Larocca *et al.*, 2004). These results are in line with the fact that ZIKV and other flaviviruses are known to replicate in the ER (Reid, Airo and Hobman, 2015); however, the specifics regarding viral assembly within the ER remain elusive (Sirohi and Kuhn, 2017).

In the ZIKV MR766-infected NSCs, the differentially regulated proteins highlighted the following biological processes: translation initiation, viral transcription, nuclear-transcribed mRNA catabolic process, SRP-dependent cotranslational protein targeting membrane and nonsense-mediated decay (NMD). We also identified pathways involving the ribosome and RNA transport as shown in Figure 5A. Moreover, the downregulated proteins were mostly involved in L13a-mediated translational silencing of Ceruloplasmin expression, GTP hydrolysis and joining of the 60S ribosomal subunit (Supplementary Figure 1), evidencing potential alterations regarding translation and associated processes.

Concerning the pathways related to Br ZIKV in infected NSCs, we observed the deregulation of mRNA metabolic processes, RNA stability processes and mRNA splicing (Figure 5B), all with the majority of proteins in each pathway found to be upregulated (Supplementary Figure 1). In both NSCs and neurospheres infected with Br ZIKV, mRNA stability and binding were enriched pathways, including AUF1 (hnRNP D0). Moreover, we also observed pathways related to metabolic alterations including biosynthesis of amino acids and glucose metabolism, as observed in Figure 5B. Altered glucose metabolism has been previously associated with ZIKV infection in relation to important aspects involving viral replication (Sanchez and Lagunoff, 2015; Gilbert-Jaramillo *et al.*, 2019). The L-lactate dehydrogenase-like protein LDHAL6A, for instance, was found upregulated in ZIKV MR766-infected NSCs, indicating increased pyruvate metabolism; though it was downregulated in Br ZIKV-infected NSCs, evidencing potential metabolic differences caused by ZIKV strains.

Figure 4. Regulation of pathways enriched in NSCs and neurospheres infected by ZIKV (Br and MR766 strains) and DENV. Heatmap showing the regulation of enriched pathways in **A. NSCs** and **B. neurospheres**, where colors represent the median fold change of proteins within the pathway.

Between NSCs and neurospheres, there are shared pathways involved with neurodevelopment, such as regulation of expression of SLITs and ROBO receptors. In NSCs, SLITs and ROBO signaling, along with transcription regulation mediated by RUNX3, presented the majority of proteins identified to be upregulated. SLITs and ROBO signaling play a role in axonal guidance, cell migration and proliferation (Dickson and Gilestro, 2006),

and RUNX3 acts in nervous system development, including the development of sensory neurons (Dykes *et al.*, 2010; Wang and Stifani, 2017).

Neurospheres infection by ZIKV MR766 affected pathways related to cell cycle regulation, as well as signaling involving NMDA receptors (NMDAr), metabolism of proteins, selective autophagy, cellular response to stress and nervous system development (Figure 6A). Regarding the NMDAr, its blockade has been shown to prevent neuronal death induced by ZIKV infection and as such, modulation of pathways involving NMDAr may be associated with neuronal damage induced by ZIKV (Costa *et al.*, 2017). Br ZIKV infection, however, showed cell cycle regulation to be enriched by the role of GTSE1 in G2/M progression after G2 checkpoint (Figure 6B) in a balance with the regulation of apoptosis. In neurospheres, ZIKV infection had effects on the metabolism of RNA, and differentially regulated proteins related to proteasomes -- which presented opposite patterns of expression when comparing ZIKV MR766 with Br ZIKV (Supplementary Figure 1) -- are a major cellular response to stress. These biological pathways can lead to effects on proteins controlling growth and proliferation, such as selenophosphate synthetase 1 (SEPHS1), found downregulated in both strains of ZIKV-infected neurospheres. SEPHS1 is essential for cellular proliferation and differentiation, and its gene knockout in *Drosophila* resulted in reduced brain size (Serras *et al.*, 2001). This evidence strengthens the association between ZIKV and congenital malformations.

Figure 5 Protein-protein interaction network from the differentially regulated proteins infected by ZIKV in NSCs. **A.** Clustered interactions of proteins modulated by ZIKV MR766 in comparison to MOCK. In red, SRP-dependent cotranslational protein targeting the membrane ($\text{Log}_{10}(\text{P})$ -16.3) and ribosome activity ($\text{Log}_{10}(\text{P})$ -12.9). In blue, cytoplasmic translational initiation ($\text{Log}_{10}(\text{P})$ -6.3) and RNA transport ($\text{Log}_{10}(\text{P})$ -6.0). In green, RNA splicing, via transesterification reactions with bulged adenosine as a nucleophile ($\text{Log}_{10}(\text{P})$ -11.2), mRNA splicing, via spliceosome ($\text{Log}_{10}(\text{P})$ -11.2). In purple, proton transmembrane

transport ($\text{Log}_{10}(P)$ -6.1). **B.** Clustered interactions of proteins modulated by Br ZIKV in comparison to MOCK. The cluster in red represents the enrichment of biosynthesis of amino acids ($\text{Log}_{10}(P)$ -9.1) and glucose metabolism ($\text{Log}_{10}(P)$ -6.2); in green, mRNA splicing ($\text{Log}_{10}(P)$ - 6.6).

Figure 6. Protein-protein interaction network identified in the differentially regulated proteins infected by ZIKV in Neurospheres. A. Clustered interaction of proteins

modulated by ZIKV MR766 in comparison to MOCK. The red cluster was enriched for L13a-mediated translational silencing of Ceruloplasmin expression ($\text{Log}_{10}(\text{P})$ -25.3), eukaryotic translation initiation ($\text{Log}_{10}(\text{P})$ -24.9) and Cap-dependent translation initiation ($\text{Log}_{10}(\text{P})$ -24.9). The blue cluster was enriched for the role of GTSE1 in G2/M progression after G2 checkpoint ($\text{Log}_{10}(\text{P})$ -22.0), separation of sister chromatids ($\text{Log}_{10}(\text{P})$ -17.9) and G2/M transition ($\text{Log}_{10}(\text{P})$ -17.9). The green one was enriched for RAB GEFs exchange GTP for GDP on RABs ($\text{Log}_{10}(\text{P})$ -5.3). And the orange one for COPI-mediated anterograde transport ($\text{Log}_{10}(\text{P})$ -7.3), Golgi-to-ER retrograde transport ($\text{Log}_{10}(\text{P})$ -7.0) and ER to Golgi Anterograde Transport ($\text{Log}_{10}(\text{P})$ -6.8).

B. Clustered interaction of proteins modulated by Br ZIKV in comparison to MOCK. The cluster in red was enriched for the cellular amino acid metabolic process ($\text{Log}_{10}(\text{P})$ -19), the role of GTSE1 in G2/M progression after G2 checkpoint ($\text{Log}_{10}(\text{P})$ -17.6) and proteasome ($\text{Log}_{10}(\text{P})$ -17.1). The cluster in blue was enriched for the HSP90 chaperone cycle for steroid hormone receptors (SHR) ($\text{Log}_{10}(\text{P})$ -5.6), mitochondrial protein import ($\text{Log}_{10}(\text{P})$ -5.4) and cellular responses to stress ($\text{Log}_{10}(\text{P})$ -5.2). The cluster in green was enriched for SRP-dependent cotranslational protein targeting to the membrane ($\text{Log}_{10}(\text{P})$ -16.6), influenza Viral RNA Transcription and Replication ($\text{Log}_{10}(\text{P})$ -15.9) and influenza Infection ($\text{Log}_{10}(\text{P})$ -15.4).

Conclusion

Despite not reaching the point of being an epidemic emergency, understanding ZIKV strains and their divergent and similar mechanisms is important not only for the development of treatment strategies but also for the comprehension of congenital syndromes associated with the Br ZIKV in the outbreak of 2015. We compared the ZIKV infection in two different models, a two-dimensional (2D) NSC culture and a 3D neurosphere culture. This allowed us to gather information regarding differentially regulated proteins and biochemical pathways shared between ZIKV strains and DENV, as well as pathways exclusive to each. These results show that the proteomic fingerprint of ZIKV infection differs greatly depending on the developmental state of neural cells, in addition to the viral strain.

Conflict of Interest

The authors declare no competing financial interests.

Author Contributions

DMS, SKR, JMN and PPG conceived and designed the study. DJG and JMN performed *in silico* proteomic analyses. JMN and JSC performed mass spectrometry experiments. GSZ performed pathway analysis and interpretation. ECL and PPG cultured, infected and differentiated iPS-derived cells. DJG and JMN interpreted the data, wrote, edited and revised the manuscript. DMS and SKR coordinated the study. All authors contributed to the final version of the manuscript.

Funding

DGJ, JMN, GSZ and DMS are supported by the São Paulo Research Foundation (FAPESP, grant numbers 2018/25439-9; 2017/25055-3; 2014/21035-0; 2018/14666-4; 2017/25588-1.

Acknowledgments

The authors thank Gabriela Vitoria, Ismael Gomes, and Paulo Baldasso for their excellent technical support and Bradley Smith, MSc for critical comments and English review support during the process.

5 CONCLUSÃO

O Zika vírus é um arbovírus pertencente à família Flaviviridae. Apesar de não constituir uma atual emergência de saúde pública, casos de infecção continuam sendo reportados e ainda existe a necessidade de se compreender as alterações causadas por tal infecção viral, incluindo as diferenças entre as cepas circulantes, de modo a desvendar as relações entre a infecção e as alterações neurológicas decorrentes, destacando o desenvolvimento da síndrome congênita, incluindo os quadros de microcefalia em neonatos de mães infectadas pela cepa brasileira de ZIKV.

Ademais, dentro do cenário atual em que estamos inseridos, com a pandemia do novo coronavírus, observa-se a importância do estudo dos vírus, a compreensão de seus mecanismos, buscando o desenvolvimento de medidas profiláticas, como as vacinas, além de tratamentos. Para tanto, modelos *in vitro* utilizando iPSCs e organoides, possibilitam a investigação relacionada com diferentes estágios do desenvolvimento.

Neste trabalho foi realizada a análise proteômica de células tronco neurais e neuroesferas infectadas com cepas brasileira e africana do ZIKV (Br ZIKV e MR766) em comparação ao DENV. Em nossas análises foi possível observar padrões distintos de alterações não só entre as cepas estudadas, mas também em relação aos modelos *in vitro*. Tais distinções podem se vincular à própria diferença em complexidade dos modelos avaliados, uma vez que as neuroesferas consistem um estágio do neurodesenvolvimento mais avançado em relação às células tronco neurais.

Com os dados obtidos, evidenciamos a presença de alterações em proteínas e processos biológicos relacionados à neurogênese, transporte celular, metabolismo de energia, ciclo celular e processamento de RNA, tanto nas NSCs como nas neuroesferas. No tocante às NSCs, cabe ressaltar as vias de sinalização envolvendo a regulação do ciclo celular e a sinalização apoptótica, além da proteína DCX, que atua na migração e diferenciação neural (Jiang et al., 2018), sendo identificada negativamente reguladas em ambas as cepas de ZIKV (ZIKV 766 e Br ZIKV), constituindo um potencial mecanismo associado às alterações neurológicas induzidas pela infecção por ZIKV.

Já em relação às neuroesferas, foram identificadas proteínas relacionadas à via de sinalização Hippo, reportada como sendo essencial para aspectos de replicação viral. Ademais, também relacionada com mecanismos envolvidos com a replicação viral (Garcia et al., 2020), foi identificada a proteína NMT1, apresentando-se positivamente regulada nas três cepas virais

(ZIKV 766, Br ZIKV e DENV) (Suwanmanee et al., 2019). Outra proteína potencialmente relevante identificada nas neuroesferas corresponde à SEPHS1, negativamente regulada em ambas as cepas de ZIKV (ZIKV 766 e Br ZIKV). De acordo com a literatura, o *knockout* desse gene *in vivo* foi associado à redução do volume cerebral (Serras et al., 2001). Deste modo a investigação de SEPHS1 em relação à infecção por ZIKV pode fornecer informações acerca das alterações neurais induzidas por tais flavivírus, especialmente no que se refere ao desenvolvimento do quadro da microcefalia.

Ademais, observamos um padrão distinto de expressão especialmente focado na modulação das vias pela cepa do Br ZIKV, que pode se relacionar com potenciais alterações relacionadas com o neurodesenvolvimento, contribuindo para a compreensão das alterações moleculares induzidas pelo ZIKV, às quais resultam em distúrbios congênitos.

Portanto, neste trabalho, com os dados de proteômica gerados, foi possível corroborar informações previamente conhecidas acerca da infecção por ZIKV e DENV, bem como a identificação de outras proteínas e processos biológicos que podem contribuir para a elucidação dos mecanismos moleculares desencadeados pela infecção por tais cepas.

8 ANEXOS

8.1 DECLARAÇÃO DE BIOÉTICA E BIOSSEGURANÇA

COORDENADORIA DE PÓS-GRADUAÇÃO
INSTITUTO DE BIOLOGIA
Universidade Estadual de Campinas
Caixa Postal 6109. 13083-970, Campinas, SP, Brasil
Fone (19) 3521-6378. email: cpgib@unicamp.br

DECLARAÇÃO

Em observância ao **§5º do Artigo 1º da Informação CCPG-UNICAMP/001/15**, referente a Bioética e Biossegurança, declaro que o conteúdo de minha Dissertação de Mestrado, intitulada ***“Perfil proteômico de células progenitoras neurais e neuroesferas infectadas com cepas de Zika vírus e Dengue vírus”***, desenvolvida no Programa de Pós-Graduação em Biologia Funcional e Molecular do Instituto de Biologia da Unicamp, não versa sobre pesquisa envolvendo seres humanos, animais ou temas afetos a Biossegurança.

Assinatura: 
Nome do(a) aluno(a): Danielle Gouvêa Junqueira

Assinatura: 
Nome do(a) orientador(a): Daniel Martins de Souza

Data: 05/06/2021

8.2 DECLARAÇÃO DE DIREITOS AUTORAIS

As cópias de artigos de minha autoria ou de minha co-autoria, já publicados ou submetidos para publicação em revistas científicas ou anais de congressos sujeitos a arbitragem, que constam na minha dissertação de mestrado intitulada “**Perfil proteômico de células progenitoras neurais e neuroesferas infectadas com cepas de Zika vírus e Dengue vírus**”, não infringem os dispositivos da lei nº 9.610/98, nem o direito autoral de qualquer editora.

Campinas, 05 de junho de 2021
